# African Food Tradition rEvisited by Research

FP7 n°245025

Start date of project: **01/09/2010**Duration: **45 months** 

Deliverable number: D 5.2.2.3

Title of deliverable: Initial report on sensory and European consumer acceptance for Group 3

Deliverable type (Report, Prototype, Demonstration, Other): Report

Dissemination level (PU, PP, RE, CO)\*: PU

Contractual date of delivery: September 2012

Actual date of delivery: April 2013

Work-package contributing to the deliverable: **WP5** 

Organization name of lead contractor for this deliverable: ESB/NRI

<u>Authors:</u> Maria Isabel Franco, Ana Patrícia Silva, Maria João Monteiro, Geneviève Fliedel, Aurelie Bechoff, Keith Tomlins and M. Manuela Pintado

# General approach

The work encompassed in this deliverable had as main objective the evaluation of sensory properties and European consumer acceptance of traditional African products from group 3 – plant based extracts for functional foods. The products selected for European studies at this stage were Bissap - *Hibiscus sabdariffa L.* and Baobab - *Adansonia digitata L.*. drinks. These results, besides the knowledge of European consumer perception about these products were also relevant to gather baseline information to support decisions concerning reengineering of the products.

AFTER project aims to revisit traditional African products, knowledge and know-how in the light of new technologies for the benefit of consumers, producers and processors in Africa and Europe. By applying European science and technology to African traditional food products, AFTER seeks to turn research into quantifiable and innovative technologies and products that are commercially viable in both European and African markets.

In order to efficiently assess the sensory properties and the European consumer preference and perception of the products the study was structured in the following steps:

# I. Bissap study:

- a. Sensory evaluation and consumer preference studies involving the Portuguese consumer for Bissap
- b. Consumer preference study involving the English consumer for Bissap
- c. Consumer preference study involving the French consumer for Bissap

# II. Baobab study:

a. Sensory evaluation and consumer preference studies involving the Portuguese consumer for Baobab

### I. Bissap study

The Bissap report consists of an introduction, materials and methods, results and conclusions. The introduction, materials and methods, are common in the three countries under review. The results will be presented separately by study and country. Finally, as conclusions it will be presented the overall findings of the study.

#### Introduction

Hibiscus sabdariffa L. is a herbaceous plant commonly known as Roselle that mainly grows in tropical and subtropical countries. The swollen calyxes, red color and cup-like, are the part of the plant of commercial interest (Mottram and Puckey 1978; De Castro and others 2004) as they are rich sources of vitamin C, phytochemicals, and are also used for making a variety of products including, infusions, food colorants, jam and particularly drinks (Gonzalez-Palomares et al. 2008; Sherif et al. 2011). Although there are different recipes, typically in Africa, the drink is made from an extract obtained by aqueous extraction from solid to solvent ratio, at temperatures between 25 and 100 °C. After filtration, sugar and others ingredients may be added depending of the region where it is consumed (Cissan, 2010, Rodrigues et al, 2011). It is consumed as cold or hot beverage (Sáyago-Ayerdi et al, 2007, Rodrigues et al, 2011) and different aroma compounds were found according to the preparation (Rodrigues et al, 2011).

The consumption of this drink is widespread in Africa and Asia, and as far as we know little appears to have been published about European consumers' acceptance, once the drink is quite unknown in Europe. In order to achieve product acceptance followed by successful market introduction, it is prime importance to gain insight in the factors determining consumers' food choice. Understanding how consumers perceive food products is critical for food companies. This information is essential for the development and marketing of new products, the reformulation of existing ones, the optimization of manufacturing processes and the establishment of specifications in quality control programs (Meilgaard et al. 1999). As consumers are not always able to say why they like a product (Elmore et al. 1999), preference mapping techniques have been widely used to answer this question (Greenhoff and MacFie 1994; Schlich 1995; Murray and Delahunty 2000; Guinard et al. 2001; Van kleef et al. 2006). Preference mapping techniques try to correlate consumer preference ratings to perceived sensory characteristics of the product in order to determine how the sensory characteristics of the product affect consumer liking (Arditti 1997; Van kleef et al. 2006). Although preference mapping is one of the most popular tools of marketing research (Urban and Hauser 1993; Van kleef et al. 2006), it has been claimed to have several limitations (ten Kleij and Musters 2003; Krishnamurthy et al. 2007). One of these limitations is that it assumes that consumers and trained assessors perceive the products in the same way. Through these techniques, consumers are only asked how much they like the product, and therefore, information about how they perceive the sensory characteristics of the product is not gathered but in fact this information is directly related with consumer perception and preference of the product. Thus, sensory information is normally obtained from a trained panel (Faye et al. 2006). However, trained assessors could describe the product differently or take into account attributes that may be irrelevant for consumers (Kleij and Musters 2003). In order to gather information

about how consumers perceive the sensory characteristics of a food product, consumer studies usually include questions about the product's sensory characteristics (Meilgaard et al. 1999). Another alternative is the use of check-all-that-apply questions (CATA).

A CATA question consists of a list of words or phrases from which respondents should select all the words they consider appropriate to describe a product. The use of a CATA question resulted in a simple and valid approach to gather information about consumers' perception of the product, including both their sensory and hedonic impression. Considering results from the present study, the use of CATA questions could be an interesting methodology to obtain a sensory map based only on consumer perception of the products and to perform external preference mapping when a sensory trained panel is not available.

The aim of the consumer studies was gathering information based on a structured focus group and on a QDA performed in Portugal, to apply afterwards Check-All-That-Apply (CATA) questions to compare consumer perception in the development of *Hibiscus sabdariffa L.* drink products between European countries, namely Portugal, United Kingdom and France. Four samples (n=4) were tested, two directly as commercial products - viz. 1 commercial syrup and 1 commercial instant drink and two produced in place from calices according traditional processes. Consumer's studies were performed in Oporto, Porto - Portugal, with 100 people from two Portuguese Catholic University Campuses, in Chatham, United Kingdom, with 120 people from the University of Greenwich and in Montpellier, France with 120 people from two canteens at the CIRAD Campus (La Recherche Agronomique pour le Développment) viz. – Baillarguet and Lavallete. Consumers were asked to score their overall liking and to answer a CATA questionnaire that included 28 sensory and hedonic terms.

The sensory evaluation of the traditional African products was performed only in Portugal by a trained assessors' panel. Sensory profiles of selected drinks were determined using a trained panel and an established sensory language. Six traditional samples (n=6) brought from Senegal were tested, two directly as commercial products - viz. 1 commercial syrup and 1 commercial instant drink and four produced according to traditional approaches from calices. Principal Component Analysis (PCA) was used based on Qualitative Descriptive Analysis (QDA) results. Sensory lexicon was generated during preliminary focus group sessions guided by a panel leader. To gather information on perceptions and attitudes of consumers towards Bissap drink, a qualitative study by using focus groups to collect data was performed intending to probe and develop knowledge on the following issues: i) most valued attributes of this drink and respective levels; ii) possible consumption situations and usage for this type of new drink. This data was analysed by conjoint analysis methods aiming to: iii) measure the important attributes for consumers and iv) determine possible different and relevant market segments for this product in Portugal.

# **Material and Methods**

# **Samples**

The Bissap samples were from three different types: Ordinary calyces or Koor variety from Senegal and Vimto variety originated from Sudanese, and syrup from Esteval, a Senegalese company and instantaneous powder "Starling" commercialized by Racine SA, France.

Traditional samples were prepared using local traditional practices under good safety conditions. Calyces were extracted in water at room temperature (typically 2 hours) (5% (m/v)) or boiled (typically 1 hour) (3,3% (m/v)). Sugar (130 g/L) was added after filtration followed by pasteurization at T=85°C for 20 minutes.

The syrup drink was prepared by dilution (1:4) of the commercial syrup (made with calyces infusions concentrated).

The instant drink was prepared after dissolving the granules in water, 10 % (m/v), at room temperature.

Six different samples (traditional and commercial) were presented to the panellists as the following:

- 1. Traditional ambient temperature Vimto infusion
- 2. Traditional boiled Vimto infusion
- 3. Traditional ambient temperature Koor infusion
- 4. Traditional boiled Koor infusion
- 5. Commercial syrup diluted 1:4
- 6. Commercial instant drink

#### **Ethical assessment and consent**

This study has been assessed and approved by the NRI Ethics Committee. Consent was signed by sensory panellists and consumers which participated in this study. Interviewers informed participants about the study and explained that their participation was entirely voluntary, that they could stop the interview at any point/time and that the responses would be anonymous.

# **Sensory evaluation**

The Bissap samples were evaluated and scored by a trained sensory panel (as described on ISO 11035:1994 Sensory analysis — Identification and selection of descriptors for establishing a sensory profile by a multidimensional approach - Standard Operation Procedure 2 (SOP 2)), according Figure 1.

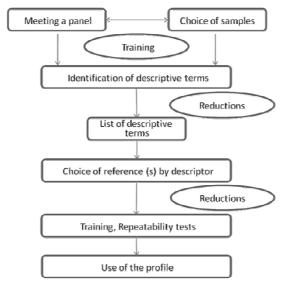

Figure 1 - Sensory profile methodology.

The panel was composed by university employees and students (n=7) previously selected according their sensory ability and familiarity with drinks (they had been trained for this type of products, during previous sessions). Sessions were conducted at sensory rooms with controlled room/air temperature and lightning. The language used for the sensory testing was Portuguese and English.

Sensory attributes were generated during preliminary focus group sessions guided by a panel leader. A total of 20 sensory attributes were developed, with correspondent references/or anchors, with panel consensus, as represented in Table 1 and Table 2, respectively.

Table 1 - Bissap "Hibiscus" Drink - Attributes definition.

During consecutive training sessions, the panel was exposed to different Bissap samples and tried to identify all (or part of) the aforementioned attributes. Subsequently, the panel was presented with selected samples of Bissap and based on the list, they had to identify and quantify the main descriptors using a 0 to 5 continuous scale (100 mm) – in which 0 stands for none and 5 for strong. At each session, six samples labelled with three digit random numbers and served in transparent plastic cups (50 mL), were present at each panellist monadically according to a balanced design. Mineral water was available for rinsing between samples.

# **Consumer study - Focus group**

In order to have some knowledge about the perceptions of consumers on Bissap drink an explorative methodology was first used. The instrument for data collection was Focus Groups, conducting according to standard procedures (Morgan, 1997) using the script for the purpose mentioned above, and a video recorder. The themes exploited in Focus Groups are presented in Table 3.

Table 3 – Topics of Focus Groups Guide

| <b>Exploited Topics of Focus Groups</b>           |
|---|
| A. Global sensory characterization of each sample |
| Taste of four blind Bissap drink samples:         |
| sample A – Cold Extraction                        |
| sample B – Instantaneous                          |
| sample C – Hot Extraction                         |
| sample D – Syrup                                  |
| B. Attitude to buy                                |
| C. Occasion of consumption                        |
| D. Motives of consumption                         |
| E. Willingness to pay                             |
| F. Local to buy                                   |
| G. Others possible applications of Bissap         |
| H. Influence of African Origin on labelling       |

A pilot focus group was implemented to test the discussion guide and then three focus groups (90-100 min) were performed between November and December (2011) with 22 recruited volunteers. The characterization of participants can be seen in Table 4.

Table 4 – Sociodemographic profile of focus groups participants

| Demographics                                    | Participants (%) |
|---|------------------|
| Male  | 46%              |
| Female  | 54%              |
| Age 18-25                                       | 36%              |
| Age 26-55                                       | 36%              |
| Age + 55  | 27%              |
| Single  | 41%              |
| Married   | 59%              |
| Higher degree education                         | 55%              |
| Secondary degree education                      | 45%              |
| Socio-Economical Status (ESOMAR guidelines): A  | 14%              |
| Socio-Economical Status (ESOMAR guidelines): B  | 36%              |
| Socio-Economical Status (ESOMAR guidelines): C1 | 23%              |
| Socio-Economical Status (ESOMAR guidelines): C2 | 23%              |
| Socio-Economical Status (ESOMAR guidelines):E2  | 5%               |

| Fruit juice consumers (requirement of recruitment)             | 100% |
|--|------|
| Responsible for buying food stuffs(requirement of recruitment) | 100% |

The focus groups were recorded in DVD and all data produced were afterwards transcript verbatim to text, and analysed by using content analysis techniques in software NVivo, to outline findings and meet research goals for this stage.

### Conjoint Analysis

Conjoint Analysis is a powerful tool to assist marketing researchers in modelling human decision making, once it quantifies the importance that people give to various attributes that underlie decisions, predicting which products (or services) people will prefer, and it reveals whether the market is sensitive or indifferent to the various features of a product (Austin, 2000).

How consumers evaluate their choices is affected by a complex set of factors that influence and shape decision process behaviour, including individual differences and environmental influences (Blackwell, 2006). As a result, evaluative criteria become product-specific manifestation of an individual or group needs, values, and so on. Conjoint analysis is well suited for the implementation of selected types of market segmentation (Green, 1991). These results allow to develop benefit-based segments to identify distinct groups consumers, such as those seeking products on the basis of price or others specific attributes (Austin, 2000).

This methodology has been widely used in food research and its efficacy and usefulness is clearly proved in order to achieve consumer's preferences. A large number of conjoint analysis studies with different food products are published, eg: pineapple juice (Finco, 2010), functional foods (Grunert, 2003; Larson, 2003), wines (Gil, 1997, Quester, 1998), olives (Moskowitz, 2005), impact of reduced salt content (Hersleth, 2011), foods processed (Cardello, 2007), food bars (Mahanna, 2009),

Because acceptability factors depend of the importance of each attribute conjoint analysis was selected as best approach. The attributes and levels were defined according with the focus groups results and market research.

The attributes generated by focus groups were also useful to be used in further sensorial research, specifically to develop CATA (Check-All-That-Apply) questionnaires.

Table 5 – Attributes and operationalization of the conjoint study

| Attributes              | Number   | Description of levels                       |
|-------------------------|----------|---|
|                         | of level |   |
| 1 – Price / L           | 4        | a) 0,99€                                    |
|                         |          | b) 1.49€                                    |
|                         |          | c) 1.99€                                    |
|                         |          | d) 2.49€                                    |
| 2 – Colour of the drink | 2        | a) Transparent red (like rosé wine)         |
|                         |          | b) Dark red (like red wine)                 |
| 3 – Calories            | 4        | a) Light (less than 18 Kcal / 100 ml)       |
|                         |          | b) Low calories (between 18 e 32 Kcal / 100 |
|                         |          | ml)   |

|                               |   | c) Slightly Caloric (between 32 e 45 Kcal / 100 ml) |
|-------------------------------|---|---|
|                               |   | d) Caloric (more than 45 Kcal /100 ml)              |
| 4 - Package information about | 2 | a) With antioxidant information                     |
| antioxidants                  |   | b) Without antioxidant information                  |
| 5 - Material Package          | 4 | a) Tetra-Pack                                       |
|                               |   | b) Glass  |
|                               |   | c) Can  |
|                               |   | d) Plastic  |
| 6 - Package Bissap            | 2 | a) Made with Bissap Flower                          |
| Information                   |   | b) Without reference to Bissap flower               |
| 7 - Package information about | 2 | a) African origin                                   |
| origin                        |   | b) No information about the product origin          |
| -                             |   | •   |

By using an orthogonal plan created by conjoint model of SPSS (version 19), thirty seven full-profile Bissap drink were produced. It was developed a questionnaire in which respondents have to evaluate the probability of buy each one of the presented profiles, by using a liker 5 points scales (1- certainly would not buy to 5 – certainly would by).

As the market segmentation presupposes heterogeneity in buyers 'preferences and ultimately choices for products, and as it can be related to person variables (Green, 1991), the questionnaire also includes socio-demographic information about participants: age, gender, educational level, socioeconomic level, job classification and frequency of juices/non-alcoholic drinks consumption.

A convenience sample of 107 responses was used in order to have reliable results.

# **Consumer study – CATA test**

Participants were recruited considering their interest and availability to participate in the study. At recruitment stage, no information about the specific aim of the study was provided. Consumer's studies were performed in Oporto, Porto - Portugal, with 100 people from two Portuguese Catholic University Campuses, in Chatham, United Kingdom, with 120 people from the University of Greenwich and in Montpellier, France with 120 people from two canteens at the CIRAD Campus (La Recherche Agronomique pour le Développment) viz. – Baillarguet and Lavallete. Consumers were asked to score their overall liking and to answer a CATA questionnaire that included 28 sensory and hedonic terms. Consumers were interviewed using the central location method (Meilgaard et al., 2007).

Figure 2 - Consumer study apparatus: Portugal, United Kingdom, France, respectively.

Four Bissap drinks were selected for consumer tasting among the samples used for sensory analysis, namely:

- 1. Traditional ambient temperature Vimto infusion
- 2. Traditional boiled Vimto infusion
- 3. Commercial syrup diluted 1:4
- 4. Commercial instant drink

Figure 3 - Bissap samples for consumer study.

The samples were selected since they were the most different among the available traditional drinks.

Consumers were asked to score their overall liking, concerning appearance, smell, taste and global appreciation, of each sample on a 9-point hedonic scale (1 = "dislike extremely, 9 = "like extremely"); sweetness of each product using the 9-point "Just About Right" (JAR scale) (1 = "Extremely less sweet than ideal", 9 = "Extremely more sweet than ideal") and their willingness to buy on a 5-point scale (1 = "certainly would not buy", 5 = "Certainly would buy"); and to answer a Check-All-That-Apply (CATA) questionnaire that included 28 sensory and emotional terms.

Consumers were asked to check all the terms they considered appropriate to describe each samples. The terms were selected based on previous studies (sensory evaluation and focus-group performed by Portuguese Catholic University), published data and marketing campaigns of Bissap in African market.

As shown in Table 6, the terms considered in the CATA questionnaire were grouped into two categories: sensory characteristics (n=16) and perceptions (n=12).

Table 6 - List of attributes considered in CATA study.

| SAMPLE                       |  |  |
|------------------------------|--|--|
| APPEARANCE                   |  |  |
| Red Colour                   |  |  |
| Pink Colour                  |  |  |
| Clear                        |  |  |
| Viscous                      |  |  |
| Fluid                        |  |  |
| SMELL AND TASTE              |  |  |
| Flowers                      |  |  |
| Fruity                       |  |  |
| Fresh herb                   |  |  |
| Cold Black Tea               |  |  |
| Raisins                      |  |  |
| Honey                        |  |  |
| Acid/Sour                    |  |  |
| Sweet                        |  |  |
| Bitter                       |  |  |
| Harsh taste                  |  |  |
| Hay                          |  |  |
| PERCEPTIONS                  |  |  |
| Natural                      |  |  |
| Artificial                   |  |  |
| Smooth                       |  |  |
| Full Bodied                  |  |  |
| Astringent (makes mouth dry) |  |  |
| Healthy                      |  |  |
| Fresh                        |  |  |
| Like an Instant Drink        |  |  |
| Watery                       |  |  |
| Strong                       |  |  |
| Diluted                      |  |  |
| Concentrated                 |  |  |

# Data analysis

An analysis of variance (ANOVA) was performed on consumer overall liking scores considering assessor and sample as fixed source of variation. Mean ratings and honestly significant differences were calculated using Tukey's test, and were considered significant when  $p \le 0.05$ .

A principal component analysis (PCA) was also performed on the correlation matrix of the means of the trained assessors' data.

All data produced of focus groups were afterwards transcript verbatim to text, and analysed by using content analysis techniques.

In order to identify groups of consumers with similar preference patterns, a hierarchical cluster analysis was performed on overall liking data. Euclidean distances and Ward's aggregation method were considered.

For the CATA study, frequencies of mention for each word were determined by counting the number of consumers that used that word to describe each Bissap drink, and Cochran's Q test was carried out for each of the 28 terms, considering sample and consumer as sources of variation to evaluate if the CATA question was able to detect differences in consumers' perception of the evaluated samples. Cochran's Q test is a nonparametric statistical test, which is used in the analysis of two-way randomized block designs to check whether k treatments have identical effects, when the response variable is binary.

A multiple factor analysis (MFA) was performed on responses to the CATA question in order to identify relationships between the terms and the samples and to get a sensory map of the samples (Bécue-Bertaut and Pagès 2008). This analysis was performed on the frequency table that contained responses for each category of terms of the CATA question, considering consumer overall liking scores as supplementary variable. In this analysis, the different categories of terms from the CATA question were considered as separate groups of data to investigate the relationship between them.

Finally, external preference mapping was used to link consumer overall liking scores and responses to the CATA question. A density plot of consumer liking was created, identifying the percentage of consumers satisfied with samples. In this plot, the points of maximum density were considered as corresponding to the ideal products.

All statistical analyses were performed using software NVivo, SPSS 19 and XLSTAT 2012.

# Results -

# I. Bissap study

# a) Sensory evaluation and consumer preference studies involving the Portuguese consumer for Bissap

# **Sensory evaluation**

Qualitative Descriptive Analysis (QDA) was performed in order to establish a sensory profile of Bissap drinks (Figure 4). Highly significant differences (P<0,001) between the samples were found for all the evaluated sensory attributes.

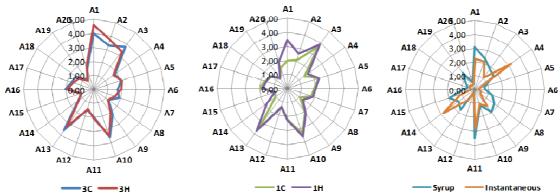

Figure 4 - Sensory profile (QDA) of Traditional ambient temperature Vimto infusion (3C) and Traditional boiled Vimto infusion (3H); Traditional ambient temperature Koor infusion (1C) and Traditional boiled Koor infusion (1H); Commercial syrup diluted 1:4 (Syrup) and Commercial instant drink (Instantaneous).

In what concerns Traditional infusions, samples are characterized by their strong colour intensity, high viscosity, floral and acid attributes. Sample 3H differs from 3C only in colour intensity (3H is higher than 3C) and in viscosity (3C is higher than 3H). Sample 1H differs from 1C only in colour intensity and viscosity attributes (1H has higher scores than 1C).

Syrup sample is represented by their strong colour intensity and high viscosity, sweet, floral and sour cherry attributes. Instant drink is real distinguished between samples by their high intensities of raspberry and sweet attributes.

Sensory profiles of samples 3Q, 3F, 1Q and 1F are more complex then sensory profiles of Syrup and Instant drink samples.

Principal component analysis (PCA) was performed to summarize the relationship between the sensory attributes and the Bissap drinks (Traditional ambient temperature Vimto infusion (3C), Traditional boiled Vimto infusion (3H), Commercial syrup diluted 1:4 (Syrup) and Commercial instant drink (Instantaneous). The first two principal components (PCs) accounted for by 76,95 % and 21,20 % of the variance of the experimental data, respectively. As shown in Figure 5, the first PC was positively correlated to floral, hay, cold black tea, raisins, bitter, acid and adstringent sensory attributes. Therefore, this PC was mainly related to Traditional ambient temperature Vimto infusion (3C) and Traditional boiled Vimto infusion (3H) samples. On the other hand, the second PC was related to sweet and sour cherry

sensory attributes being associated with Commercial syrup diluted 1:4 sample and raspeberry attribute with Commercial instant drink sample.

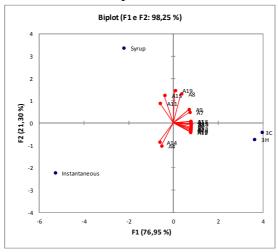

Figure 5 - Principal Component Analysis of trained assessor's sensory data (representation of sensory attributes and Bissap samples).

# **Focus Groups**

# 1. Global Characterization of Bissap Drink

From all samples presented the most appreciated one was sample B, followed by sample C, sample D, and the less appreciated was the sample A. Briefly is presented a characterization of each sample based on the speech of the participants:

Sample A (cold extraction) – Related with winter; very sweet taste; strong taste and negative aroma; dark and artificial colour; very acid in the end after taste.

Sample B (instantaneous) – Related with summer; equilibrated taste; watery; negative colour; taste associated to pomegranate; good taste but bad appearance.

Sample C (hot extraction) – Taste similar with A sample, very sweet and acid in the aftertaste; negative aroma; good colour; it was identified hibiscus.

Sample D (syrup) – Very sweet. Taste similar with sample C. Reasonable colour.

As it is presented in Table 7, regarding to the description of attributes two groups were generated according to the positive and negative opinion of participants.

Table 7 – Frequency of principle attributes generated during the Focus Groups

| Attributes | Frequency | of |
|------------|-----------|----|
|            | responses |    |
| Sensory    |           |    |
| Sweetness  | 64%       |    |

| Astringency                  | 32%  |
|------------------------------|------|
| Acid                         | 32%  |
| Watery                       | 23%  |
| Bitter                       | 23%  |
| <b>Food Related Positive</b> |      |
| Pomegranate                  | 100% |
| Fruity                       | 23%  |
| Cranberry / Blackberry       | 18%  |
| Hibiscus                     | 14%  |
| Blackcurrant                 | 14%  |
| Tomato                       | 9%   |
| Cherry                       | 9%   |
| Sour Cherry                  | 5%   |
| Food Related Negative        |      |
| Wine                         | 9%   |
| Non-Food Related Negative    |      |
| Syrup/Medication             | 18%  |
| Poison                       | 5%   |
| Plastic                      | 5%   |
|                              |      |

# 2. Attitude to Buy

In this item it was evaluated the frequency of consumption if this beverage was available on the market. The results show that almost half participants (46%) seem predisposed to buy the Bissap drink between 2/3 times a week; 36% between 1/2 in a month; 9% would buy it in a sporadic way; 5% once a week and 5% would not buy it.

# 3. Occasion and Local for consumption

The Table 8 below is a resume of the main occasions and locals for Bissap Drink consumption for Portuguese consumers.

Table 8 – Identified occasion and locals for Bissap drink consumption

| Occasion              | for | Frequency |
|-----------------------|-----|-----------|
| consumption           |     | (%)       |
| Breakfast             |     | 50%       |
| Lunch                 |     | 41%       |
| Middle of afternoon   |     | 64%       |
| Dinner                |     | 32%       |
| Locals for Consumpti  | on  |           |
| Home                  |     | 95%       |
| Terrace               |     | 50%       |
| Café/bar              |     | 50%       |
| Macrobiotic Restauran | t   | 41%       |
| SPA                   |     | 27%       |
| Gymnasium             |     | 23%       |
|                       |     |           |

# 4. Motives for consumption

Healthy reasons were the main reason presented for bissap drink consumption by Portuguese consumers. This motive is mostly presented by women's (75%) contrasting with sensory properties which man's valuated more (90%). Nevertheless, novelty is an important factor for both genders (50% each one). Participants knew in advanced that this drink have in their composition a high level of antioxidants and as these components might be important for our health, so they would be willing to consume it even if the taste is not so pleasant they expected. This result is in line with the results of Sparke and Menrad (2009), where health is also identified as one of the motives for functional drinks consumption. Nevertheless, taste/sensory properties and perceived health benefits are two important considerations for food acceptance and it has been discussed in functional foods context by some authors. According to Verbeke (2007) consumers in general are hardly willing to compromise on the taste of functional foods for health. Sabbe and others (2009) concluded that for Belgium consumer's acceptance and intention to purchase açaí fruit drinks is driven most by their sensory pleasure and less by the health benefits.

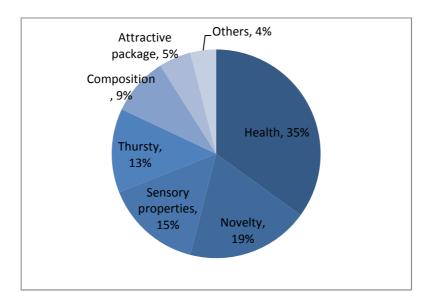

Figure 6 - Reasons for bissap drink consumption by Portuguese

# 5. Willingness to pay

Regarding willingness to pay for Bissap Drink, about 60% of participants imagine themselves buying 1 L packages in supermarkets. The range price varies between  $0.70 \le 2 \le 1$  L, although the most part of them are between  $1.5 \le 2 \le 1$  L.

Moreover, the others 40% imagine themselves buying small packages of 0,33cl in one of these specific locals: supermarkets or cafés/bars. In this cases the price varies between 0,35−0,50€.

Package has an obviously impact on product price. Consequently participants talked spontaneously about their preferences of package material: 14% prefers glass bottles for this drink rather the most part of them prefers tetra-pack. Cans were referred as not applicable for this type of drink.

Some participants also referred that would be available to pay more than the value appointed if i) the package would be very attractive ii) the package contain relevant information about the product; and iii) if this drink really have high level of antioxidants and consequently health benefits.

# 6. Locals to Buy

Consists on locals where consumers would like to buy Bissap drink, almost all (82%) would like to have this drink available in supermarkets (82%), also cafés (27%), bares (23%) and restaurants (9%) were mentioned. In addition convenience shops, pharmacy and gas pump shops where also referred each one representing 5% of frequency.

# 7. Possible applications

The Table 9 below resume the applications proposed by the participants and the frequency as well. The suggestions presented were grouped in two distinct groups according the type of application.

Table 9 – Possible application product type of Bissap

| <b>Applications Type</b> | <b>Product Suggestion</b>        | Frequency |
|--------------------------|----------------------------------|-----------|
|                          | Yogurt                           | 27%       |
|                          | Gelatine                         | 23%       |
| Agro-Industries          | Ice-creams                       | 18%       |
|                          | To mix with non-alcoholic drinks | 14%       |
|                          | To make Sangria                  | 5%        |
|                          | Topping/Dressing                 | 50%       |
| House maid               | Jelly                            | 41%       |
|                          | Sauce                            | 5%        |

# 8. Influence of the origin

Concerning the importance and influence to consumers' choice of drinks origin's in labelling, it is verified that consumers can be grouped in two different clusters: i) for some participants (9%, mans, age between 18-25) labels and their information is not at all important, they do not read or look it, so for them do not really matter if it says or not the origin of the product; ii) for the others participants (81%) a general agreement exists about the importance in having this information in packaging labelling. One of reasons presented to justify is because consumer like to be informed about the product, knowing their origin for example, or even some background about that; another reason referred is because Africa has a less intensive agriculture not abusing on pesticides and some consumers can connect this fact to a healthy agricultural products, which means that this information can add value to products. Additionally, it was also said that as Africa is much related with solidarity campaigns, it could be also an advantage to include in labelling the origin of the drink, in order to influence the consumer's choice. Nevertheless, for these participants it is clear that they would not be influenced by that information on their choices.

# **Conjoint Analysis**

From the evaluation given by the respondents to the hypothetical product and applying the Conjoint Module of Statistical software package SPSS 19, we estimate the part-worths of

each of the product attributes as an aggregate for all the consumers. The results are presented in the next Table.

Table 10 – Part-worth of levels and relative importance of attributes

| Attribute                     | Level                                   | Part-<br>worth | Relative importance (%) |  |
|-------------------------------|---|----------------|-------------------------|--|
| Origin Information            | African Origin                          | -,017          | 5,088                   |  |
|                               | Without information about Africa origin | in,017         |                         |  |
| Drink Color                   | Red dark color (type red wine)          | -,004          | 5,877                   |  |
|                               | Light red color (type rose wine)        |                |                         |  |
| Bissap Information            | Made with Bissap Flower                 | ,052           | 6,465                   |  |
|                               | -,052                                   |                |                         |  |
| Antioxidant With Antioxidants |   |                | 6,726                   |  |
| Information                   | Without antioxidants information        | -,036          |                         |  |
| Calories                      | Light (less than 18 Kcal/ 100ml)        | ,166           | 25,675                  |  |
|                               | Slighly Caloric (19-33 Kcal/100ml)      | ,159           |                         |  |
|                               | Moderatly Caloric (34-44 Kcal/100ml)    | -,074          |                         |  |
|                               | Caloric (more than 45 Kcal/100ml)       | -,251          |                         |  |
| Package                       | Can                                     | -,075          | 23,979                  |  |
|                               | Glass                                   | ,050           |                         |  |
|                               | Plastic                                 | -,091          |                         |  |
|                               | Tetra-pack                              | ,116           |                         |  |
| Price                         | 0.99€ / L                               | -,278          | 26,190                  |  |
|                               | 1.49€ / L                               | -,556          |                         |  |
|                               | 1.99€ / L                               | -,834          |                         |  |
|                               | 2.49€ / L                               | -1,112         |                         |  |

The most salient attribute for these Portuguese consumers related to Bissap drink is the Price, which had the highest relative importance (26,2%). This is not so surprising results because the price is much related with food choice and purchase. Also in others studies developed with this methodology the price has been the first attribute most valuated by consumers for different products (Finco, 2010, Mesías, 2010) and identified as one of the main factors for non-consumers not buy functional drink (Sparke and Menrad, 2009). It is interesting to note that there is an inverse relation between price and part-worth, as higher the price is the lowest the part-worth. Consumers were also significantly affected by the "calories", and the relative importance for this feature reached 25,7%. In this case the lowest nutritional value is somehow health related, especially to weight loss. Again an inverse relation is notice between the part-worths and the calories value. With similar importance appears afterwards the "package", in terms of material package, with a relative importance of 23,9%. It is interesting to notice that for this group of consumers the package information is not so important as the antioxidant information, bissap information or either the reference to the African origin of the product. This was also verified with Sparke and Menard (2009) for a functional orange drink: the packaging holds a relative importance higher than the health claims. A possible explanation for this is given by Larsen (2003) where he indicates that the perception of the healthiness of functional foods is more dependent on their perception of the nutritional qualities of the based-product than on any type of health claim. All the others evaluated attributes doesn't seem to be crucial for purchasing intention once their relative importance's are between 5% and 6%.

The preferred bissap drink would be which, from each combination of attributes, offers respondents the great utility. In this case the ideal product corresponds to Bissap drink at a price of 0.99€/L, Light (less than 18 Kcal/100ml), Tetra-pack package, with antioxidants information on package, with Bissap information on package, light red colour drink. This group of consumers did not valorise the information about African origin of the beverage.

In some way it seems contradictory that the African origin information expressed in the package is the attribute with the lowest relative importance for Portuguese consumers. According to the perception from the focus groups this attribute was classified as very important for consumers, adding value to the product, and making some the difference when purchasing. But when we go further and it is evaluated in a group of attributes, and consumers are forced to choice a profile product, the result it is not anymore a priority for consumers.

#### 1. Reliability

From the evaluation of the respondents to the hypothetical products, and applying the "Conjoint" module of statistical software package SPSS 19, the part-worths of each of the product's attributes were estimated. Consistency of participant's response, which means if the model fit individual data, can be evaluated by calculating the Pearson correlation coefficient (R) between the original ratings given by respondents and those determined by the model (Malhotra, 1996). The resulting value (R = 0.962) indicated that the model predicted the consumer's preferences well. Also the Kendall's tau for Holdouts coefficient, which is an

indicator of internal validity, has a higher value of 0.738 for a significance of 0.038, which indicates a good predictive ability.

Table 11 – Correlations between observed and estimated preferences

|                            | Value | Sig. |
|----------------------------|-------|------|
| Pearson's R                | ,962  | ,000 |
| Kendall's tau              | ,857  | ,000 |
| Kendall's tau for Holdouts | ,738  | ,038 |

# 2. Consumers performance segmentation

The market segmentation is the process of finding groups of costumers who are similar on some specific criterion of relevance to the product strategic context (Lilien, 2007). In this study a cluster analysis was used to classify consumers into homogenous clusters, according to their preferences.

The calculations were performed with the Cluster module of the statistical software package SPSS 19, using first a hierarchical cluster analysis by using Ward's method and afterwards a non-hierarchical methodology - the k-means cluster procedure. The inputs used were the coefficients of each respondent's utility function.

A four-cluster solution was chosen as being in accord with: coefficient of agglomeration; dendogram observation, size of the segments, and number of iterations.

Having determined homogenous segments of consumers with respect to their preference functions, we calculate the relative importance for different consumer segments. The results are presented in Table 12.

Table 12 – Consumer segments performance profiling

| Average attributes | Clusters (segments) |          |          |          |  |  |
|--------------------|---------------------|----------|----------|----------|--|--|
| importance         | 1 (n=24)            | 2 (n=36) | 3 (n=19) | 4 (n=19) |  |  |
| Price              | 52%                 | 24%      | 22%      | 16%      |  |  |
| Origin Information | 5%                  | 6%       | 4%       | 5%       |  |  |
| Drink Colour       | 5%                  | 9%       | 3%       | 4%       |  |  |
| Bissap Information | 4%                  | 10%      | 4%       | 5%       |  |  |

| Antioxidant Information | 5%   | 7%   | 4%   | 5%   |
|-------------------------|------|------|------|------|
| Calories                | 11%  | 24%  | 52%  | 13%  |
| Package                 | 18%  | 20%  | 11%  | 52%  |
| Total                   | 100% | 100% | 100% | 100% |

Cluster 1 is the smallest segment of the study and is distinguished by the greatest relative importance to the "Price". The relative importance's of all the other attributes (unless the Package) are close to each other far from the Price importance. We denominate this segment "Price Sensitive".

Cluster 2 encompasses the greatest fraction of consumers. For this segment there is no principal attribute, but it presents intermediate and similar importance value at three different attributes: price, package and calories. Due to this fact, we denominated this segment "Consumers without particular preferences".

Cluster 3 represents about one fifth of the consumers and corresponds to whom give the highest relative importance to the Calories. Besides the price, which is the second place of relative importance, all the other attributes are not so relevant to this group and all have lower values. We determined to call this group "Body Concerned"

Cluster 4 represents one fifth of the consumers and for this group the most important attribute is distinctly the package. All the other attributes have lower (and similar) relative importance. We denominated this segment "Package Attracted".

An analysis of variance showed that all segments differed significantly from each other with respect to the all attributes, unless "Origin information" and " "Antioxidant Information", which according to the clusters analysis are not relevant attributes for these group of consumers.

Table 13 – Analysis of Variance (ANOVA)

|                    | Cluster        | Cluster |                | Error  |        | Sig.  |
|--------------------|----------------|---------|----------------|--------|--------|-------|
| Attributes         | Mean<br>Square | df      | Mean<br>Square | df     |        |       |
| Price              | 0.667          | 3.000   | 0.011          | 94.000 | 61.903 | 0.000 |
| Origin Information | 0.001          | 3.000   | 0.003          | 94.000 | 0.555  | 0.646 |
| Drink Colour       | 0.018          | 3.000   | 0.003          | 94.000 | 6.343  | 0.001 |
| Bissap Information | 0.032          | 3.000   | 0.003          | 94.000 | 9.635  | 0.000 |

| Antioxidant Information | 0.005 | 3.000 | 0.002 | 94.000 | 2.528  | 0.062 |
|-------------------------|-------|-------|-------|--------|--------|-------|
| Calories                | 0.660 | 3.000 | 0.008 | 94.000 | 78.083 | 0.000 |
| Package                 | 0.666 | 3.000 | 0.010 | 94.000 | 67.195 | 0.000 |

According to this results the dimensions that can better distinguish the clusters are the "Calories", followed by "Package" and after by the "Price". All the other attributes are not so valorized by consumers. This is in agreement with the most evaluated attributes by the four clusters achieved.

Table 14 presents details of the four clusters in terms of their sociodemographic characteristics and frequency drink consumption. This information complements that on their preferences and allows one to a better approach a typology of consumers.

Table 14 – Sociodemographic and consumption pattern parameters (%) of four consumer cluster identified

| Variables        |                             | Cluster | Sig |     |     |                     |
|------------------|-----------------------------|---------|-----|-----|-----|---------------------|
| variables        |                             | 1       | 2   | 3   | 4   | (Chi <sup>2</sup> ) |

|                  | Unemployed                  | 0%      | 11% | 5%  | 5%  |                     |

| Principle<br>member of<br>income | yes                        | 46% | 53% | 47% | 42% | 0,887 |
|----------------------------------|----------------------------|-----|-----|-----|-----|-------|
|                                  | no                         | 54% | 47% | 53% | 58% | 3,007 |
| Drink                            | 1 (daily to 4 times/week)  | 91% | 81% | 74% | 79% |       |
| Consumption Frequency            | 2 (1-3 times/month)        | 8%  | 14% | 21% | 16% | 0,808 |
| requency                         | 3 (less than once a month) | 0%  | 5%  | 5%  | 5%  |       |
| NIO -£                           | 1 (0-2 children)           | 13% | 17% | 16% | 5%  |       |
| N.° of dependents                | 2 (3 children)             | 46% | 53% | 58% | 58% | 0,850 |
|                                  | 3 (>3 children)            | 42% | 30% | 26% | 37% |       |

The main characteristics of each segment are:

Cluster 1 – Price Sensitive – This segment can be characterized with the consumers that have the highest drink consumption frequency, the lowest level of education and do not include unemployed consumers.

Cluster 2 – Consumers without particular preferences - This is the group that has the highest level of persons with more than 36 years and also has the largest percentage of unemployed.

Cluster 3 – Body Concerned - the majority of this consumers segment are women, between 18 and 36 years and with 3 children.

Cluster 4 – Package Attracted – almost all consumers from this group have children and belongs to a lower/medium social classes, according to the ESOMAR criteria, but contrary what is normally expected, this group has the consumers with the highest degree of education.

According to Lilien (2007), a meaningful segmentation should satisfy three managerial criteria: 1) Homogeneity within the segments and Heterogeneity between them; 2) Identifiability: segments should be accessible and 3) Parsimony: the segmentation should be cost effective to implement. Although the possibility of distinguish four different clusters and characterize them, it was not possible to find significative differences (according to chi square analyses) between the clusters, so heterogeneity was not found, at least with the sociodemographic characteristics used on this study. The socioeconomic level is the variable that is closer to have significance, maybe using a biggest sample would be possible achieve significant differences. So, further and deep studies are necessary to obtain consumers segmentation significance, it might be to evaluate more and different types of sociodemographic characteristics or habits of consumption to achieve

# **Consumer study – CATA**

### 1. Consumer Overall liking scores

As shown in Table 15, there were significant differences (P<0,001) in the overall liking scores. Regarding all samples used during consumer study it was possible to verify that all of the drinks were on the acceptable range since the mean scores were between 4 (dislike slightly) and 6 (like moderately). Instant drink was the most preferred followed by Syrup, 3H and 3C, in a decrease order of magnitude.

Table 15 - Mean overall acceptability scores for the Bissap drinks tested.

| AC1 |      |
|-----|------|
|     | Samp |

| Sample        | Mean  | Mean Groups |   |   |
|---------------|-------|-------------|---|---|
| Instantaneous | 5,780 | Α           |   |   |
| Syrup         | 5,400 | Α           | В |   |
| 3H            | 4,980 |             | В | С |
| 3C            | 4,770 |             |   | С |

<sup>6 -</sup> Like moderately

# 2. Consumers segmentation using Hierarchical cluster analysis

The hierarchical cluster analysis (Ward method) identified three groups of consumers that scored the overall liking scores of the samples differently: Cluster 1 with 51 individuals, Cluster 2 with 8 and Cluster 3 with 41 consumers (Figure 7).

There were significant differences (P < 0.001) in the overall liking of the clusters, indicating different preference patterns (Table 16). Consumers in Cluster 1 gave the highest overall acceptability scores to Instant drink followed by Syrup, 3C and 3H; Cluster 2 includes consumers that gave highest overall acceptability scores to 3C followed by Instantaneous, 3H and Syrup and; Cluster 3 includes consumers that accepted in a decrease order of magnitude the Syrup followed by 3H, 3C and Instant drink.

<sup>5 -</sup> Neither like nor dislike

<sup>4 -</sup> Dislike slightly

<sup>\*</sup> Means with the same letter are not significantly different

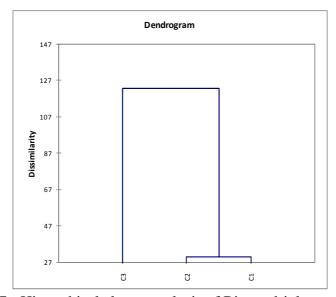

Figure 7 - Hierarchical cluster analysis of Bissap drinks consumers.

Table 16 - Bissap samples distributed into Cluster sorted by increasing order of preference.

Objects sorted by increasing preference order:

| Cluster1   | Cluster2   | Cluster3      |
|------------|------------|---------------|
| 3H         | Syrup      | Instantaneous |
| 3C         | 3H         | 3C            |
| Syrup      | Instantane | (3H           |
| Instantane | :3C        | Syrup         |

# 3. Check-All-That-Apply Question

Consumers were asked to evaluate the samples and to check all the terms that they considered appropriate to describe the sensory characteristics and emotional associations/perceptions using a questionnaire comprising 28 related terms. The most frequently selected terms were considered as the most used by consumers to describe the samples.

Table 17 shows the frequency in which each of the terms of the CATA question was used to describe the evaluated samples. The most frequently used terms were "red colour", "fruity", "artificial", "fluid", "clarity", "pink colour", "sweet", "strong" and "concentrated". Meanwhile, the least used term was "hay".

Significant differences (P<0,0001) were found in the number of terms used by consumers to describe the samples. As shown in Table 17, the largest number of terms was used to describe Samples 3H, 3C followed by Instantaneous drink and Syrup. This could be explained considering that consumers were more motivated to describe the samples that they considered more complex. Regarding the different categories in the CATA question, consumers used the terms related to the sensory characteristics of samples with a higher frequency than those

within the emotional associations; suggesting that consumers' perception was mostly centred in their sensory characteristics.

These results suggest that this type of question was able to detect differences in consumer's perception of the Bissap drinks.

Table 17 - Results of the Check-All-That-Apply question. Frequencies for each attribute and evaluated samples.

|                        | Samples            |      |      |       |               |                      |                                  |  |

|                        | Diluted            | 5    | 13   | 12    | 40            | 70                   |                                  |  |
|                        | Concentrated       | 44   | 33   | 22    | 1             | 100                  |                                  |  |
|                        | Total terms/sample | 647  | 636  | 569   | 588           |                      |                                  |  |
|                        | Average number of  |      |      |       |               |                      |                                  |  |
|                        | terms used in CATA | 6,47 | 6,36 | 5,69  | 5,88          |                      |                                  |  |
|                        | question/sample    |      |      |       |               |                      |                                  |  |

Considering that the three identified clusters showed different preference patterns, they could have also used the terms of CATA question differently. Therefore, Multiple Factor Analysis (MFA) was carried on out considering CATA counts for groups of consumers.

Mulltipple factor analysis (MFA) was performed on responses in each category to the CATA question in order to identify relationships between the terms and the samples and to get a sensory map of the samples.

In what concerns sensory characteristics category, the first two dimensions of the MFA accounted for 81,54% of the variance of the experimental data; representing 61,17% and 20,38% of the variance for the first and second dimension, respectively. Regarding emotional associations category, the first two dimensions of the MFA accounted for 94,08% of the variance of the experimental data; representing 82,93% and 11,15% of the variance for the first and second dimension, respectively. Thus, most of the variance was explained by the first dimension.

Figure 8 a) shows the representation of the sensory terms from the CATA question in the first and second dimensions of the MFA of CATA counts. The first dimension of the MFA was

positively correlated to terms red colour, viscous, cold black tea and raisins related to 3H sample; and to acid, bitter and hay attributes associated with 3C sample; and negatively correlated to terms pink colour, clarity and floral attributes related to instant drink sample. On the other hand, the second dimension was positively correlated to sweet, fruity and fresh herb representative of syrup sample.

Figure 8 b) shows the representation of emotional associations terms from the CATA question in the first and second dimensions of the MFA of CATA counts. The first dimension of the MFA was positively correlated to terms fresh, instantaneous, diluted and watery being associated with Instant drink sample; and negatively correlated to concentrated and bond descriptors from 3H sample. The second dimension was positively associated to 3C sample with rough and strong terms; and negatively linked to natural and smooth attributes, which described Syrup sample.

Since different categories of terms were included in the CATA question, samples were characterized not only in terms of sensory attributes, but also considering consumer perception of different aspects of the samples (emotional associations) and the overall liking of each one. The relationship between the categories of terms from the CATA question provided interesting information. As shown in Figure 9, all the categories were located close to each other in the first dimension of the MFA, which suggests that they provided similar information. MFA accounted for 89,65% of the total variance of the experimental data; representing 75,82% and 13,83% of the variance for the first and second dimension respectively. However, it is interesting to note that the group of terms related to sensory characteristics and emotional associations were highly correlated. This suggests that sensory characteristics seemed to have influenced consumers' emotional responses to Bissap drinks. Moreover, these two groups of terms were highly correlated to overall liking; suggesting that sensory characteristics were the main determinants of consumers' hedonic and emotional response toward the evaluated Bissap drinks and that the most liked products raised more positive emotional responses in consumers.

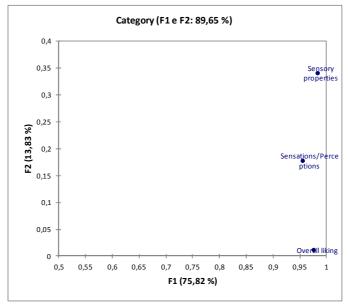

Figure 9 - Representation of the categories of terms from the CATA question and the overall liking scores in the first two dimensions of the MFA.

The approach of considering different categories of terms in a CATA question seems promising for studying the relationship of consumers' perception of sensory and non-sensory attributes of products. This is an interesting approach for R&D, Marketing and Communication departments to develop strategies for launching a new/or changed product to market. So, to more finely compare the level of agreement/disagreement between all categories considered on CATA question and overall liking scores, MFA was employed using the first two dimensions of the three maps created. Figure 10 represents the location of the Bissap drinks as optimal product determined for each of the three types of categories on the first two MFA factors (individual factor map).

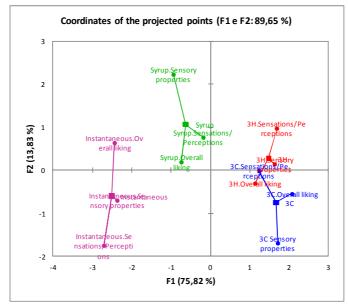

Figure 10 - Products' spatial representation /products' configuration (first two dimensions) determined using sensory characteristics, emotional associations and overall liking scores of consumers.

# 4. External Preference Mapping

Figure 11 shows the external preference map based on samples' configuration in the MFA of CATA counts. The contour plot shows lines corresponding to different percentage of consumers who scored their overall liking under a 9-point hedonic scale (1 = "dislike extremely, 9 = "like extremely").

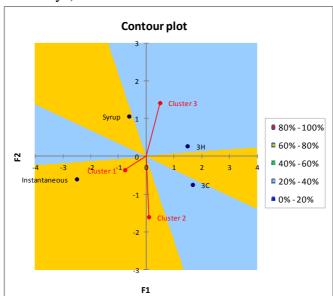

Figure 11 - External Preference Map based on consumers' perception of the samples, i.e., considering consensus samples' coordinates in the MFA of consumers' responses to the CATA.

The external preference map showed that Syrup and Instantaneous were located in an area where the percentage of consumers who liked them range between 60 and 80%, which is in

agreement with their mean overall liking scores. Samples 3H and 3C were located in zones where the consumers scored their overall liking lower than 6 ranged from 20% to 40%.

The advantage of this approach is that drivers of liking could be identified based only on consumers' perception of samples. As shown in Figures 8 and 10, the areas of maximum liking were correlated to products characterized with "positive" sensory attributes and emotional terms. Therefore, the application of external preference mapping based on consumers' responses to CATA questions seem to be a simple and quick alternative for companies that have difficulties to use trained assessors' panels. Despite their good results, it is important to take into account that responses to CATA questions are in terms of counts and not intensities as measured by a trained panel using intensity scales and therefore could not be considered supplementary methodologies.

# 5. Internal Preference Mapping

Figure 12 shows the internal preference map based on consumers' overall liking of Bissap drinks.

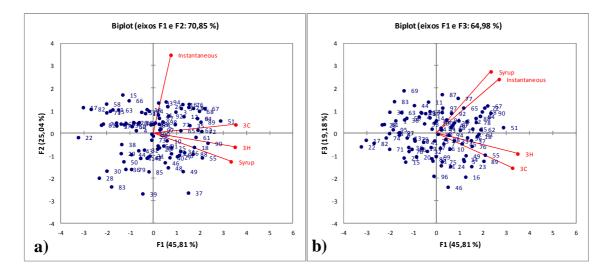

Figure 12 - Internal Preference Map based on consumers' overall liking samples.

The internal preference map showed three groups of consumer's preference: Group I - samples Syrup & Instantaneous with 26%, Group II - 3H & 3C with 25% and Group III - with no opinion with 49%, of overall liking scores.

# b) Consumer preference study involving the English consumer for Bissap Consumer study

# 1. Consumer Overall liking scores

As shown in Table 18, there were significant differences (P<0,001) in the overall liking scores.

Table 18 - Mean overall liking scores, concerning appearance, smell, taste, global appreciation; sweetness and willingness to buy, for the Bissap drinks tested.

| Samples         | Average (Appearance) | Groups |   |  |
|-----------------|----------------------|--------|---|--|
| Syrup           | 7,212                | Α      |   |  |
| Cold extraction | 6,938                | Α      |   |  |

| Samples         | Average (Taste) |       | Groups |   |  |
|-----------------|-----------------|-------|--------|---|--|
| Syrup           |                 | 6,009 | Α      |   |  |
| Inst. Juice     |                 | 5,920 | Α      |   |  |
| Cold extraction |                 | 5,035 |        | В |  |
| Hot extraction  |                 | 4,522 |        | В |  |

| Samples         | Average (Overall) | Groups |   |   |
|-----------------|-------------------|--------|---|---|
| Syrup           | 6,212             | Α      |   |   |
| Inst. Juice     | 6,035             | Α      |   |   |
| Cold extraction | 5,381             |        | В |   |
| Hot extraction  | 4,814             |        |   | С |

| Samples         | Average (Sweetness) | Groups |  |  |
|-----------------|---------------------|--------|--|--|
| Syrup           | 5,646               | Α      |  |  |
| Cold extraction | 4,982               | В      |  |  |
| Inst. Juice     | 4,841               | В      |  |  |
| Hot extraction  | 4,770               | В      |  |  |

| Samples         | Average (WTB) | Groups |   |   |  |
|-----------------|---------------|--------|---|---|--|
| Syrup           |               | 3,080  | Α |   |  |
| Inst. Juice     |               | 2,991  | Α |   |  |
| Cold extraction | :             | 2,434  |   | В |  |
| Hot extraction  | :             | 2,221  |   | В |  |

Regarding all samples used during consumer study it was possible to verify that all of the drinks were on the acceptable range since the mean scores were between 4 (dislike slightly) and 7 (like slightly), according to a 9-point scale, with the exception for the willingness to buy where the mean scores were between 2 (Probably would not buy) and 3 (I have some doubts if I would buy it or not) in a 5-point scale.

According to overall liking, syrup drink was the most preferred followed by instant drink, traditional cold extraction and traditional hot extraction drink, in a decrease order of magnitude. In what concerns sweetness, samples cold extraction, instant drink and hot extraction had an ideal concentration of sugar. Syrup had a slightly more sugar than ideal. The results achieved for the willingness to buy were equal or below 3 (I have some doubts if I would buy it or not). Consumers preferred syrup and instant drink followed by cold and hot

# 2. Consumers segmentation using Hierarchical cluster analysis

extraction samples.

The hierarchical cluster analysis (Ward method) identified three groups of consumers that scored the overall liking scores of the samples differently: Cluster 1 with 44 individuals, Cluster 2 with 54 and Cluster 3 with 15 consumers (Figure 13).

There were significant differences (P < 0.001) in the overall liking of the clusters, indicating different preference patterns (Table 19). Consumers in Cluster 1 gave the highest overall acceptability scores to syrup followed cold extraction sample, hot extraction sample and instant drink; Cluster 2 includes consumers that gave highest overall acceptability scores to instant drink followed syrup, cold extraction and hot extraction and; Cluster 3 includes consumers that accepted in a decrease order of magnitude the instant drink followed by syrup, hot extraction and cold extraction.

As shown in Figure 14 Cluster 1 represents the "Bissap likers" (39%), Cluster 2 the "Commercial Bissap likers" (48%) and Cluster 3 the "Bissap dislikers" (13%), consumers. The products rated below five were considered as "disliked" and above five as "liked".

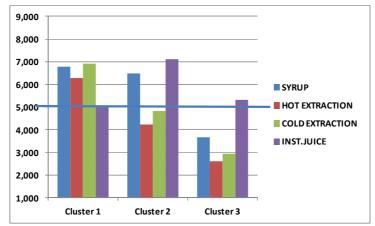

Figure 14 - Mean consumer acceptance of Bissap by cluster type.

# 3. Check-All-That-Apply Question

Consumers were asked to evaluate the samples and to check all the terms that they considered appropriate to describe the sensory characteristics and emotional associations/perceptions using a questionnaire comprising 28 related terms. The most frequently selected terms were considered as the most used by consumers to describe the samples.

Table 20 shows the frequency in which each of the terms of the CATA question was used to describe the evaluated samples.

The most frequently used terms were "red colour", "pink colour", "clarity", "fluid", "flowers", "fruity", "acid", "sweet", "natural", "artificial", "smooth", "healthy", "fresh", "strong" and "concentrated". Meanwhile, the least used term was "hay".

Significant differences (P<0,0001) were found in the number of terms used by consumers to describe the samples. As shown in Table 20, the largest number of terms was used to describe the drinks obtained by hot extraction and cold extraction followed by syrup and instant drink. This could be explained considering that consumers were more motivated to describe the samples that they considered more complex. Regarding the different categories in the CATA question, consumers used the terms related to the sensory characteristics of samples with a higher frequency than those within the emotional associations; suggesting that consumers' perception was mostly centred in their sensory characteristics.

#### AFTER (G.A n°245025) – Deliverable D 5.2.2.3 Initial report on sensory and European consumer acceptance for Group 3

These results suggest that this type of question was able to detect differences in consumer's perception of the Bissap drinks.

Table 20 - Results of the Check-All-That-Apply question. Frequencies for each attribute and evaluated samples.

Considering that the three identified clusters showed different preference patterns, they could have also used the terms of CATA question differently. Therefore, Multiple Factor Analysis (MFA) was carried on out considering CATA counts for groups of consumers.

Mulltiple factor analysis (MFA) was performed on responses in each category to the CATA question in order to identify relationships between the terms and the samples and to get a sensory map of the samples.

Concerning the sensory characteristics category, the first two dimensions of the MFA accounted for 95,58% of the variance of the experimental data; representing 73,31% and 22,26% of the variance for the first and second dimension, respectively. Regarding the emotional associations category, the first two dimensions of the MFA accounted for 95,58% of the variance of the experimental data; representing 80,25% and 15,33% of the variance for the first and second dimension, respectively. Thus, most of the variance was explained by the first dimension.

Figure 15 a) shows the representation of the sensory terms from the CATA question in the first and second dimensions of the MFA of CATA counts. The first dimension of the MFA was positively correlated to terms acid, cold black tea, viscous, harsh taste and hay related to hot extraction sample; and to raisins and bitter attributes associated with cold extraction

sample; and negatively correlated to terms pink colour, clarity and fruity attributes related to instant drink sample. On the other hand, the second dimension was positively correlated to sweet, flowers and honey representative of syrup sample.

Figure 15 b) shows the representation of emotional associations terms from the CATA question in the first and second dimensions of the MFA of CATA counts. The first dimension of the MFA was positively correlated to terms concentrated, full bodied, astringent and strong being associated with cold and hot extraction samples; and negatively correlated to diluted, watery, like an instant beverage and artificial descriptors from instant drink sample; and with smooth and fresh terms associated to syrup sample.

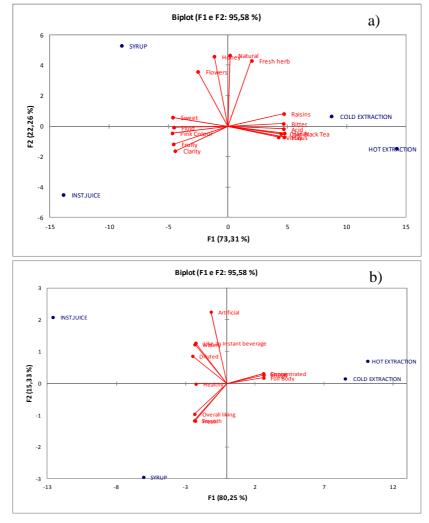

Figure 15 - Multiple Factor Analysis on the Check-All-That-Apply questions a) representation of the attributes for sensory characteristics category and b)

Since different categories of terms were included in the CATA question, samples were characterized not only in terms of sensory attributes, but also considering consumer perception of different aspects of the samples (emotional associations) and the overall liking of each one. The relationship between the categories of terms from the CATA question provided interesting information. As shown in Figure 16, all the categories were located close to each other in the first dimension of the MFA, which suggests that they provided similar

information. MFA accounted for 96,57% of the total variance of the experimental data; representing 82,19% and 14,38% of the variance for the first and second dimension, respectively. However, it is interesting to note that the group of terms related to sensory characteristics and emotional associations were highly correlated. This suggests that sensory characteristics seemed to have influenced consumers' emotional responses to Bissap drinks. Moreover, these two groups of terms were highly correlated to overall liking; suggesting that sensory characteristics were the main determinants of consumers' hedonic and emotional response toward the evaluated Bissap drinks and that the most liked products raised more positive emotional responses in consumers.

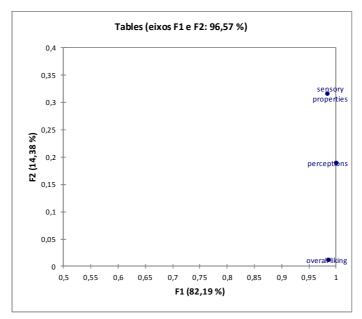

Figure 16 - Representation of the categories of terms from the CATA question and the overall liking scores in the first two dimensions of the MFA.

The approach of considering different categories of terms in a CATA question seems promising for studying the relationship of consumers' perception of sensory and non-sensory attributes of products. This is an interesting approach for R&D, Marketing and Communication departments to develop strategies for launching a new/or changed product to market. So, to more finely compare the level of agreement/disagreement between all categories considered on CATA question and overall liking scores, MFA was employed using the first two dimensions of the three maps created. Figure 17 represents the location of the Bissap drinks as optimal product determined for each of the three types of categories on the first two MFA factors (individual factor map).

# $AFTER \ (G.A\ n^o245025) - Deliverable\ D\ 5.2.2.3$ Initial report on sensory and European consumer acceptance for Group 3

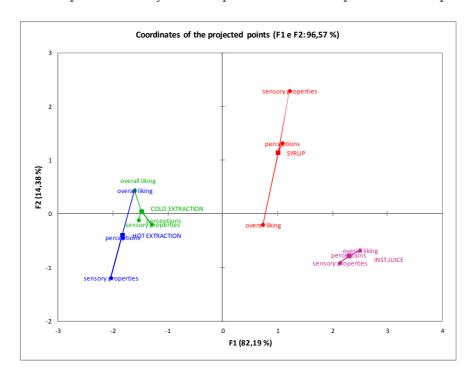

Figure 17 - Products' spatial representation /products' configuration (first two dimensions) determined using sensory characteristics, emotional associations and overall liking scores of consumers.

# 4. External Preference Mapping

Figure 18 shows the external preference map based on samples' configuration in the MFA of CATA counts. The contour plot shows lines corresponding to different percentage of consumers who scored their overall liking under a 9-point hedonic scale (1 = "dislike extremely").

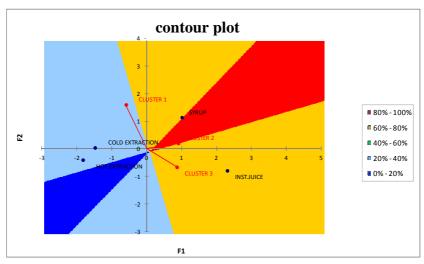

Figure 18 - External Preference Map based on consumers' perception of the samples, i.e., considering consensus samples' coordinates in the MFA of consumers' responses to the CATA.

The external preference MAP showed that Syrup and Instantaneous were located in an area where the percentage of consumers who liked them range between 60 and 100%, which is in agreement with their mean overall liking scores. Samples hot extration and cold extraction were located in zones where the consumers scored their overall liking lower than 6 ranged from 20% to 40%.

The advantage of this approach is that drivers of liking could be identified based only on consumers' perception of samples. As shown in Figures 15 and 17, the areas of maximum liking were correlated to products characterized with "positive" sensory attributes and emotional terms. Therefore, the application of external preference mapping based on consumers' responses to CATA questions seem to be a simple and quick alternative for companies that have difficulties to use trained assessors' panels. Despite their good results, it is important to take into account that responses to CATA questions are in terms of counts and not intensities as measured by a trained panel using intensity scales and therefore could not be considered supplementary methodologies.

#### 5. Internal Preference Mapping

Figure 19 shows the internal preference map based on consumers' overall liking of Bissap drinks.

# AFTER (G.A n°245025) – Deliverable D 5.2.2.3 Initial report on sensory and European consumer acceptance for Group 3

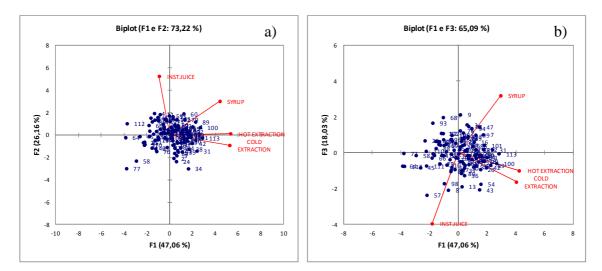

Figure 19 - Internal Preference Map based on consumers' overall liking samples.

The internal preference map showed three groups of consumer's preference: Group I - cold and hot extraction with 31%, Group II - syrup with 27%, Group III - instant drink with 23% and Group IV with no opinion representing 19%, of overall liking scores.

# c) Consumer preference study involving the French consumer for Bissap Consumer study

# 1. Consumer Overall liking scores

As shown in Table 21, there were significant differences (P<0,001) in the overall liking scores.

Table 21 - Mean overall liking scores, concerning appearance, smell, taste, global appreciation; sweetness and willingness to buy, for the Bissap drinks tested.

# Means with the same letter are not significantly different

Regarding all samples used during consumer study it was possible to verify that all of the drinks were on the acceptable range since the mean scores were between 4 (dislike slightly) and 7 (like slightly), according to a 9-point scale, with the exception for the willingness to buy where the mean scores were between 2 (Probably would not buy) and 3 (I have some doubts if I would buy it or not) in a 5-point scale.

According to overall liking, syrup was the most preferred followed by instant drink, cold extraction and hot extraction, in a decrease order of magnitude. In what concerns sweetness, samples cold extraction, instant drink and hot extraction had an ideal concentration of sugar. Syrup had a slightly more sugar than ideal.

The results achieved for the willingness to buy were equal or below 3 (I have some doubts if I would buy it or not). Consumers preferred syrup followed by cold extraction, hot extraction and instant drink samples.

# 2. Consumers segmentation using Hierarchical cluster analysis

The hierarchical cluster analysis (Ward method) identified three groups of consumers that scored the overall liking scores of the samples differently: Cluster 1 with 47 individuals, Cluster 2 with 51 and Cluster 3 with 22 consumers (Figure 20).

There were significant differences (P < 0.001) in the overall liking of the clusters, indicating different preference patterns (Table 22). Consumers in Cluster 1 gave the highest overall acceptability scores to syrup followed by cold extraction sample, hot extraction sample and instant drink; Cluster 2 includes consumers that gave highest overall acceptability scores to instant drink followed syrup, cold extraction and hot extraction and; Cluster 3 includes consumers that accepted in a decrease order of magnitude the hot extraction sample followed by cold extraction, syrup and instant drink samples.

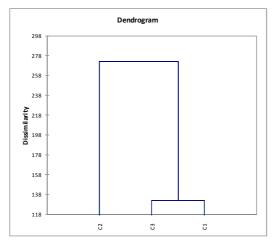

Figure 20 - Hierarchical cluster analysis of Bissap drinks consumers.

Table 22 - Bissap samples distributed into Cluster sorted by increasing order of preference.

| Cluster 1       | Cluster 2       | Cluster 3       |
|-----------------|-----------------|-----------------|
| INST.JUICE      | HOT EXTRACTION  | INST.JUICE      |
| COLD EXTRACTION | COLD EXTRACTION | SYRUP           |
| HOT EXTRACTION  | SYRUP           | HOT EXTRACTION  |
| SYRUP           | INST.JUICE      | COLD EXTRACTION |

As shown in Figure 21 Cluster 1 represents the "Bissap likers" (39%), Cluster 2 the "Commercial Bissap likers" (43%) and Cluster 3 the "traditional Bissap likers" (18%), consumers.

The products rated below five were considered as "disliked" and above five as "liked".

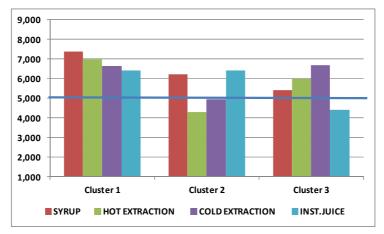

Figure 21 - Mean consumer acceptance of Bissap by cluster type.

# 3. Check-All-That-Apply Question

Consumers were asked to evaluate the samples and to check all the terms that they considered appropriate to describe the sensory characteristics and emotional associations/perceptions using a questionnaire comprising 28 related terms. The most frequently selected terms were considered as the most used by consumers to describe the samples.

Table 23 shows the frequency in which each of the terms of the CATA question was used to describe the evaluated samples.

The most frequently used terms were "red colour", "pink colour", "clarity", "fluid", "flowers", "fruity", "raisins", "acid" "sweet", "natural", "artificial", "fresh", "strong", "diluted" and "concentrated". Meanwhile, the least used term was "like an instant beverage" followed by "bitter".

Significant differences (P<0,0001) were found in the number of terms used by consumers to describe the samples. As shown in Table 23, the largest number of terms was used to describe hot extraction sample followed by cold extraction, syrup and instant drink samples. This could be explained considering that consumers were more motivated to describe the samples that they considered more complex. Regarding the different categories in the CATA question, consumers used the terms related to the sensory characteristics of samples with a higher frequency than those within the emotional associations; suggesting that consumers' perception was mostly centred in their sensory characteristics.

These results suggest that this type of question was able to detect differences in consumer's perception of the Bissap drinks.

Table 23 - Results of the Check-All-That-Apply question. Frequencies for each attribute and evaluated samples.

# AFTER (G.A n°245025) – Deliverable D 5.2.2.3 Initial report on sensory and European consumer acceptance for Group 3

|                                     | Concentrated             | 57             | 42              | 14    | 1                   | 114                  |                               |                                     |
|                                     | Total terms/sample       | 789            | 772             | 750   | 736                 |                      |                               |                                     |
|                                     | Average number of terms  |                | ,               |       |                     |                      |                               |                                     |
|                                     | used in CATA             |                |                 |       |                     |                      |                               |                                     |
|                                     | question/sample          | 6,58           | 6,43            | 6,25  | 6,13                |                      |                               |                                     |

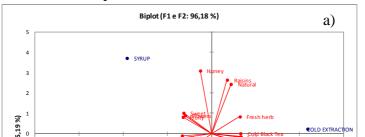

Considering that the three identified clusters showed different preference patterns, they could have also used the terms of CATA question differently. Therefore, Multiple Factor Analysis (MFA) was carried on out considering CATA counts for groups of consumers.

Mulltiple factor analysis (MFA) was performed on responses in each category to the CATA question in order to identify relationships between the terms and the samples and to get a sensory map of the samples.

In what concerns sensory characteristics category, the first two dimensions of the MFA accounted for 96,18% of the variance of the experimental data; representing 81% and 15,19% of the variance for the first and second dimension, respectively. Regarding emotional associations category, the first two dimensions of the MFA accounted for 98,24% of the variance of the experimental data; representing 75,24% and 22,99% of the variance for the first and second dimension, respectively. Thus, most of the variance was explained by the first dimension.

Figure 22 a) shows the representation of the sensory terms from the CATA question in the first and second dimensions of the MFA of CATA counts. The first dimension of the MFA was positively correlated to terms acid, viscous, harsh taste, bitter and hay related to hot extraction sample; and to cold black tea and fresh herb attributes associated with cold extraction sample; and negatively correlated to terms pink colour, clarity and fluid attributes related to instant drink sample. On the other hand, the second dimension was positively correlated to sweet, flowers, fruity and honey representative of syrup sample.

Figure 22 b) shows the representation of emotional associations terms from the CATA question in the first and second dimensions of the MFA of CATA counts. The first dimension of the MFA was positively correlated to terms like an instant beverage, diluted, artificial and watery being associated with instant drink sample; and to the term smooth for the syrup sample; and negatively correlated to concentrated, full body, rough and strong descriptors from cold and hot extraction samples.

Page **50** sur **83** 

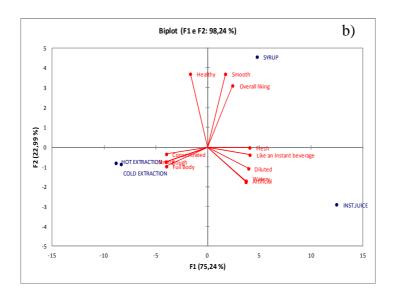

Figure 22 - Multiple Factor Analysis on the Check-All-That-Apply questions a) representation of the attributes for sensory characteristics category and b) representation of the attributes for emotional association category.

Since different categories of terms were included in the CATA question, samples were characterized not only in terms of sensory attributes, but also considering consumer perception of different aspects of the samples (emotional associations) and the overall liking of each one. The relationship between the categories of terms from the CATA question provided interesting information. As shown in Figure 23, all the categories were located close to each other in the first dimension of the MFA, which suggests that they provided similar information.

MFA accounted for 97,83% of the total variance of the experimental data; representing 83,47% and 14,36% of the variance for the first and second dimension respectively. However, it is interesting to note that the group of terms related to sensory characteristics and emotional associations were highly correlated. This suggests that sensory characteristics seemed to have influenced consumers' emotional responses to Bissap drinks. Moreover, these

two groups of terms were highly correlated to overall liking; suggesting that sensory characteristics were the main determinants of consumers' hedonic and emotional response toward the evaluated Bissap drinks and that the most liked products raised more positive emotional responses in consumers.

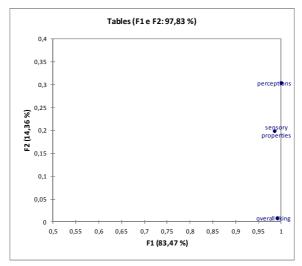

Figure 23 - Representation of the categories of terms from the CATA question and the overall liking scores in the first two dimensions of the MFA.

The approach of considering different categories of terms in a CATA question seems promising for studying the relationship of consumers' perception of sensory and non-sensory attributes of products. This is an interesting approach for R&D, Marketing and Communication departments to develop strategies for launching a new/or changed product to market. So, to more finely compare the level of agreement/disagreement between all categories considered on CATA question and overall liking scores, MFA was employed using the first two dimensions of the three maps created. Figure 24 represents the location of the Bissap drinks as optimal product determined for each of the three types of categories on the first two MFA factors (individual factor map).

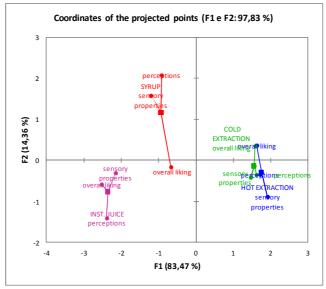

Figure 24 - Products' spatial representation /products' configuration (first two dimensions) determined using sensory characteristics, emotional associations and overall liking scores of consumers.

# 4. External Preference Mapping

Figure 25 shows the external preference map based on samples' configuration in the MFA of CATA counts. The contour plot shows lines corresponding to different percentage of consumers who scored their overall liking under a 9-point hedonic scale (1 = "dislike extremely, 9 = "like extremely").

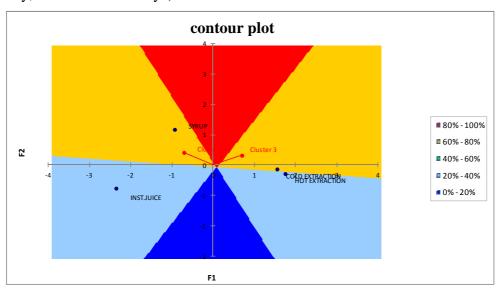

Figure 25 - External Preference Map based on consumers' perception of the samples, i.e., considering consensus samples' coordinates in the MFA of consumers' responses to the CATA.

The external preference map showed that syrup and cold extraction samples were located in an area where the percentage of consumers who liked them range between 60 and 80%, which is in agreement with their mean overall liking scores. Samples hot extraction and instant drink were located in zones where the consumers scored their overall liking lower than 6 ranged from 20% to 40%.

The advantage of this approach is that drivers of liking could be identified based only on consumers' perception of samples. As shown in Figures 22 and 24, the areas of maximum liking were correlated to products characterized with "positive" sensory attributes and emotional terms. Therefore, the application of external preference mapping based on consumers' responses to CATA questions seem to be a simple and quick alternative for companies that have difficulties to use trained assessors' panels. Despite their good results, it is important to take into account that responses to CATA questions are in terms of counts and not intensities as measured by a trained panel using intensity scales and therefore could not be considered supplementary methodologies.

# 5. Internal Preference Mapping

Figure 26 shows the internal preference map based on consumers' overall liking of Bissap drinks.

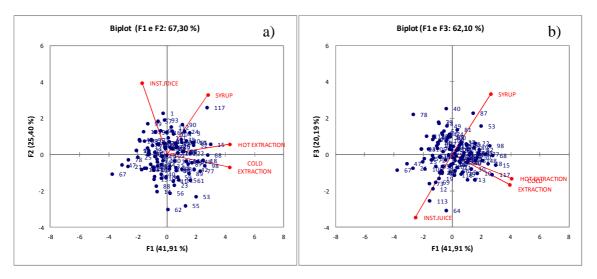

Figure 26 - Internal Preference Map based on consumers' overall liking samples.

The internal preference map showed three groups of consumer's preference: Group I - cold and hot extraction samples with 27,5%, Group II –instant drink with 25%, Group III – syrup with 22,5% and Group IV with no opinion representing 25%, of overall liking scores.

#### **Conclusions**

The Bissap drink is not commonly consumed in Europe and even unknown to the general public. However due to its composition it might be a great potential to be considered a functional drink which probably increases the consumer interests and market acceptance. In consumer behaviour about food, one of the main challenges is to identify the important factors for consumer acceptance and choice, and that is the goal of this study related to Bissap drink for European consumers.

Comparing the results achieved in each country it is possible to verify, in what concerns hedonic study, two clusters: the first one composed by Portugal and the second by France and United Kingdom, according to the similarities obtained. Cluster 1 represents 29,4 % and Cluster 2 70,6% of consumers interviewed. Cluster 1 preferred instant drink and cluster 2 syrup drink . Cluster 1, in terms of ideal sweetness preferred instant drink followed by hot extraction drinks and, their attitude to buy falls on instant drink. Cluster 2, in what concerns ideal sweetness preferred cold extraction followed by instant drink and hot extraction drinks.

#### AFTER (G.A n°245025) – Deliverable D 5.2.2.3 Initial report on sensory and European consumer acceptance for Group 3

Syrup is slightly sweeter than the other samples. In terms of their attitude to buy, they preferred syrup drink.

CATA questionnaire results revealed that is possible to establish an European consumer profile of *Hibiscus sabdariffa L.* drinks. Results from Portugal, France and United Kingdom are quite similar for all categories under study, namely sensory properties and emotions/perceptions attributes. Regarding sensory attributes, instant drink is described with pink colour and clarity; syrup with sweet; hot extraction drink with viscous and cold extraction with bitter, attributes. In what concerns emotions/perceptions, instant drink is characterized with the terms like an instant beverage, diluted and watery; syrup with smooth; hot extraction drink with concentrated and full bodied and cold extraction with strong, attributes.

Highly significant differences were found in the frequencies in which CATA terms were used for describing the four samples, suggesting that this methodology was able to detect differences in consumer perception of the drinks.

Considering results from the present study, the use of CATA questions could be an interesting and simple methodology to get an insight on consumer perception of a food product. Using this methodology, a map of the samples could be generated taking only consumer perception of the products.

The use of CATA questions could be a simple way to perform external preference mapping when a sensory trained panel is not available or when there is not enough time to train a sensory panel. In this way, the use of the CATA question could consist on a complementary technique to traditional preference mapping.

These technologies seem to be promising for studying the relationship of consumers' perception of sensory and non-sensory attributes of products. This is an interesting approach for R&D, Marketing and Communication departments to develop strategies for launching a new/or changed product to market.

# AFTER (G.A n°245025) – Deliverable D 5.2.2.3 Initial report on sensory and European consumer acceptance for Group 3

| Hedonic   |                     | PT  | FR   | ик   |

| CATA questionnaire                                |                     | PT  | FR   | UK   |
|   | instantaneous juice | pink colour, clarity, floral  | pink colour, clarity, fluid  | pink colour, clarity, fruity   |
| Sensory properties                                | syrup               | sweet, fruity, fresh herb   | sweet, flowers, fruity,<br>honey   | sweet, flowers, honey  |
|   | hot extraction      |   | acid, viscous, harsh taste,<br>bitter, hay   | acid, cold black tea, viscous,<br>harsh taste, hay   |
|   | cold extraction     | acid, bitter, hay   | cold black tea, fresh herb   | raisins, bitter  |
| Emotions/Perceptions                              | instantaneous juice |   | like an instant beverage,<br>diluted, artificial, watery   | diluted, watery, like an instant beverage, artificial  |
|   | syrup               | natural, smooth   | smooth   | smooth, fresh  |
|   | hot extraction      | concentrated, full bodied   | concentrated, full bodied, astringent, strong  | concentrated, full bodied, astringent, strong  |
|   | cold extraction     | bitter, strong  | concentrated, full bodied, astringent, strong  | concentrated, full bodied, astringent, strong  |

So the present results collected as baseline of consumer perception and acceptance of traditional hibiscus based drinks allowed to confirm the similarities of consumer profile among three European countries (Portugal, England and France) concerning the same drinks and will support the reengineering of Hibiscus drinks performed in the next steps. Finally, the new methodologies approaches implemented in these studies showed efficiency and high discriminatory value, which prove to be a good tool in this type of studies and high applicability in following consumer tests in the AFTER project.

#### I. Baobab study

a) Sensory evaluation and consumer preference studies involving the Portuguese consumer for Baobab

#### Introduction

The Baobab tree has an Arabic history, and belongs to the Bombacaceae family and Adansonia gender. There are eight species in the world including *Adansonia digitata L*. which is found in Senegal. This species is encountered in many African zones and has a long life. In many parts of Africa tubers, fruits, seeds, leaves and flowers of this plant are identified as common ingredients in traditional dishes in rural and urban areas. Also, baobab is an important source of income for Senegalese people and solely valorised in traditional ways.

From its English common name baobab by translation, the fruit is probably derived from the Arabic bu hibab, which means "fruit with several seeds». This fruit is a poly sperm berry, ovoid, with ligneous epicarp. The numerous linked seeds coated with whitish pulp are generally dried.

Baobab fruit is called "Bouy" or Monkey bread is widely used by Senegalese people and it is consumed in different forms. The pulp is probably the most important foodstuff in baobab fruit because of the strongest economic potential as compared to the remaining parts.

Figure 27 - Baobab fruit: outside, inside the outer shell and Baobab tree.

The ripe fruit pulp is naturally dehydrated and ivory coloured. It appears as a dry, mealy powder. Baobab is a popular food source. The fruit pulp is commonly sucked, chewed or made into a drink when mixed with water or milk, either with or without sugar, or as a supplement to mix with staple food such as corn meal and cassava. Other uses for baobab pulp include sauces for food, hair rinse, milk curdling agent and a sub-stitute for cream of tartar, among other things. When burned, it is a good repellent for cattle flies. The pulp is very nutritious. Arnold et al. (1985) reported that with an average of 8.7% moisture, the pulp contains about 74% carbohydrates, 3% proteins, 9% fibers, 6% ash and only 0.2% fat. The content of pectin is approximately 56% (Nour et al., 1980), which is why the pulp is traditionally used as a base for jam making. It is also characterized by a high vitamin C (ascorbic acid), calcium, phosphorus and potassium content. The acidulous taste is attributed to the presence of organic acids, such as citric acid, tartaric acid, malic acid and succinic acids.

Baobab fruit pulp has a particularly high antioxidant capability mainly because of its high natural vitamin C content, which is equivalent to 6 oranges per 100 g. Antioxidants protect the cells of organisms from damage by free radicals. A deficiency of vitamin C weakens the immune system and promotes the susceptibility to disease. Deficiency of vitamin C also results in scurvy. The recommended daily allowance (RDA) for ascorbic acid is 75 mg for women and 90 mg for men. If we consider that baobab has an ascorbic acid content of 300 mg per 100 g pulp, the oral intake of 25 and 30 g, respectively is able to provide the daily vitamin C allowance required by humans. Additionally, vitamin C aids the bodily uptake of iron and calcium, of which the fruit pulp contains more than double than the same amount of milk. Therefore, in some areas, it is used as a milk substitute for babies.

#### Domestic (African) Uses

The dry pulp is either eaten fresh or used to add to gruels on cooling after cooking – a good way of preserving the vitamin contents. It can also be ground to make a refreshing drink with a pleasing wine-gum flavour. In Tanzania, it is added to aid fermentation of sugar cane for beer making (Fleuret, 1980).

When the fruit is ripe, the pulp is removed from the fibres and seeds by kneading in cold water: the resulting emulsion is seived. This is then added to thick grain preparations to make thinner gruels. The cattle-owning Fulani and the Hausa of northern Nigeria use the fruit pulp emulsion to mix with milk as a drink.

Pulp can be stored for fairly long periods for use in soft drink production but it needs airtight containers. Storage is improved by the use of sodium metabisulphite (Ibiyemi et al., 1988). It can also be frozen if ground to a powder (Obizoba and Amaechi, 1993). Baobab powder mixtures are commonly available in many public markets, but quality can be poor and some can be fraudulent.

Fruit pulp is usually sundried, but occasionally fermented, for use in cooking.

#### Uses in the US and Europe

Baobab fruit pulp, due to the combination of health claims (such as prebiotic and antioxidant functions, the high calcium content, and the anti-inflammatory properties) and food technological functions (because of its high pectin and fiber content, baobab fruit pulp gives beverages a thicker consistency and can be also used as filler), is a very interesting candidate for a new generation of functional foods and drinks.

Baobab fruit pulp can be particularly interesting as an ingredient for smoothies, which are a kind of thick fruit juice with a high content of fruit pulp.

From July 2008, "An exotic fruit with six times the vitamin C of an orange can be sold in Britain after an EU ruling. Baobab fruit has twice as much calcium as milk and is very high in antioxidants, iron and potassium. It will not be sold as a whole fruit as the shell is too hard to crack, instead it will be available in cereal bars and smoothies. The fruit had not been allowed into the UK because legislation prevents the importation of food which has not been commonly consumed in the EU before 1997. All new foods have to be formally approved before they can go on sale. The baobab fruit won approval

following heavy lobbying from PhytoTrade Africa, an organisation that promotes fair trade."

Food companies increasingly base their product development, positioning, advertisement and communication strategies on consumer perception (Faye et al., 2006; Van Trijp et al., 2007). In this context, understanding how consumers describe the sensory characteristics of food products is highly valuable for food companies.

Traditionally, information about the sensory characteristics of a food product has been obtained using trained assessors' panels. This information is extremely valuable during product development for optimizing the products' formulation (Carr et al., 2001). However, trained assessors could describe the product differently or take into account attributes that may be irrelevant for consumers (Ten Kleij and Musters, 2003). Thus, in order to gather a better understanding of consumers' perception of food products it is necessary to study how consumers perceive and describe individual and multi-attribute changes in food products' sensory characteristics (Carr et al., 2001). Moreover, according to Dubois and Giboreau (2006) an inventory of the linguistic resources used in different languages and different senses for different food products is needed in order to better contrast consumers' experiences with trained assessors' data. Obtaining vocabularies directly from consumers has been traditionally considered tedious and difficult to interpret due to several drawbacks such as bias due to the interviewer, consumers' difficulty in describing the product's sensory characteristics and difficulty of analyzing consumers' heterogeneous responses (Piggot et al., 1990). However, some simple methodologies, such as free listing and check-all-that-apply questions, have been recently introduced to consumer science, which could be useful to identify consumers' vocabulary. One of the most novel methodologies that has been developed for gathering information about consumers' perception of the sensory characteristics of food products is the use of check-all-that-apply questions (CATA). A CATA question consists of a list of words or phrases from which respondents should select all the words they consider appropriate to describe a product. This type of question has been used in consumer studies to determine which sensory attributes consumers perceive in a food product (Adams et al., 2007; Dooley et al., 2010; Ares et al, 2010).

The aim of the present work was gather information about sensory profile by a trained panel by QDA approach and explore sensory and emotional attributes by small focus groups to apply CATA questions to study consumer perception in the development of *Adansonia digitata L*. drinks, and to compare results with those achieved using a trained assessors' panel. Four samples (n=4) were tested including three commercial ones - Commercial juice from Esteval, Commercial syrup from Esteval and Commercial syrup from Kumba and one prepared according traditional recipe - viz. Traditional boiled instantaneous powder,

A consumer study was performed with 100 people from a public local shopping center; who were asked to score their overall liking and to answer a CATA questionnaire that included 29 sensory and hedonic terms. Besides, the samples were evaluated by a trained assessors' panel. Sensory profiles of selected drinks were determined using a

trained panel (n=8) and an established Baobab drink sensory language. Sensory attributes were generated during preliminary focus group sessions guided by a panel leader.

#### **Material and Methods**

#### **Samples**

The Baobab samples for sensory tests were from three different types: Commercial juice - Esteval; Syrups from Esteval and Kumba and instantaneous powder (no reference). Four different samples (traditional and commercial) were presented to the panellists as the following:

- 1. Traditional boiled instantaneous powder
- 2. Commercial juice from Esteval
- 3. Commercial syrup from Esteval
- 4. Commercial syrup from Kumba

Traditional sample was prepared using local traditional practices under good safety conditions. Aqueous powder sample was boiled (62,5 g/L), cooled and filtered. Sugar (140 g/L) was added after filtration.

#### Ethical assessment and consent

This study has been assessed and approved by the NRI Ethics Committee. Consent was signed by sensory panellists and consumers which participated in this study. Interviewers informed participants about the study and explained that their participation was entirely voluntary, that they could stop the interview at any point/time and that the responses would be anonymous.

# **Sensory evaluation**

The Baobab samples were evaluated and scored by a trained sensory panel (as described on ISO 11035:1994 Sensory analysis — Identification and selection of descriptors for establishing a sensory profile by a multidimensional approach - Standard Operation Procedure 2 (SOP 2)), according Figure 28.

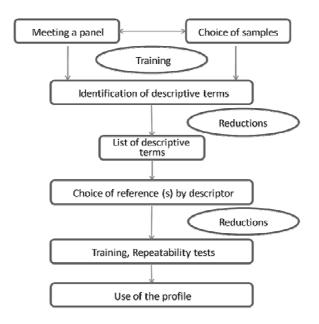

Figure 28 - Sensory profile methodology applied to Baobab samples

The panel was composed by university employees and students (n=8). Said subjects were selected according their sensory ability and familiarity with drinks. Sessions were conducted at sensory rooms with controlled room/air temperature and lightning. The language used for the sensory testing was Portuguese and English.

Sensory attributes were generated during preliminary focus group sessions guided by a panel leader. A total of 13 sensory attributes were developed, with correspondent references/or anchors, with panel consensus, as represented in Table 24 and Table 25, respectively.

Table 24 - Baobab Drink - Attributes definition.

# **Baobab Drink - Attributes definition**

| ATTRIBUTES   | DEFINITION   |
|--|--|
| APPEARANCE   |  |
| TURBIDITY (0-weak, 5-strong)                                     | is the "optical property that causes light to be scattered scattered and absorbed rather than transmitted in straight and absorbed rather than transmitted in straight lines through the sample.   |
| VISCOSITY (1-low, 5-high)  | in everyday terms (and for fluids only), viscosity is "thickness". Thus, water is "thin", having a lower viscosity, while honey is "thick", having a higher viscosity.   |
| ODOUR EVALUATION   |  |
| ODOUR/SMELL  |  |
| HERBACEOUS   | herbaceous: General term (see also "vegetal") for a product with   |
| grass (0-absent, 5-strong)                                       | "green," "grassy" or "hay-like" aroma or flavor. green: the aromatic associated with unprocessed vegetation, such as fruits and grains; this term is related to raw, but has the additional character of hexenals, leaves, and grass. grassy: grainy aromatic with some green character of freshly   |
| hay (0-absent, 5-strong)   | mowed grass (after cutting the grass). hay-like: the aromatic associated with air-dried grain or vegetation.   |
| FRUITY   |  |
| cooked fruit pear/quince<br>(marmalade) (0-absent, 5-<br>strong) | aromas and taste that associated with cooked fruit - baked, jammy.   |
| TASTE EVALUATION   |  |
| TEXTURE IN MOUTH   |  |
| viscosity (1-low, 5-high)  | in everyday terms (and for fluids only), viscosity is "thickness". Thus, water is "thin", having a lower viscosity, while honey is "thick", having a higher viscosity.   |
| FLAVOUR  |  |
| acid (0-absent, 5-strong)  | the taste stimulated by acids, such as citric, malic, phosphoric, etc.   |
| sweet (0-absent, 5-strong)                                       | the taste stimulated by sucrose and other sugars, such as fructose, glucose, etc.  |
| TASTE  |  |
| grass (0-absent, 5-strong) hay (0-absent, 5-strong)              | herbaceous: General term (see also "vegetal") for a product with "green," "grassy" or "hay-like" aroma or flavor. green: the aromatic associated with unprocessed vegetation, such as fruits and grains; this term is related to raw, but has the additional character of hexenals, leaves, and grass. grassy: grainy aromatic with some green character of freshly mowed grass (after cutting the grass). |
|  | hay-like: the aromatic associated with air-dried grain or vegetation.  |
| FRUITY   |  |
| cooked fruit pear/quince<br>(marmalade) (0-absent, 5-<br>strong) | aromas and taste that associated with cooked fruit - baked, jammy.   |
| raisins (0-absent, 5-strong)                                     | aromatic associated with a grape of any of several varieties that has been dried in the sun or by artificial heat.   |
| OTHERS SENSATIONS  |  |
| adstringent (0-absent, 5-strong)                                 | the shrinking or puckering of the tongue surface caused by substances such as tannins.   |

Table 25 - Baobab Drink - References/Anchors.

|                               | REFERENCES/ANCHORS |                                    |  |
|-------------------------------|--------------------|------------------------------------|--|
| APPEARANCE                    |                    |                                    |  |
| TURBIDITY (0-weak, 5-strong)  | 1 - water          | 5 - Baobab powder sample           |  |
| VISCOSITY (1-low, 5-high)     | 1 - water          | 5 - Baobab powder sample           |  |
| ODOUR EVALUATION              |                    |                                    |  |
| ODOUR/SMELL                   |                    |                                    |  |
| HERBACEOUS                    |                    |                                    |  |

| acid (0-absent, 5-strong)     | 0 - water          | 5 - Baobab commercial juice sample |  |
| sweet (0-absent, 5-strong)    | 0 - water          | 5 - Esteval Syrup sample           |  |
| TASTE                         |                    |                                    |  |
| HERBACEOUS                    |                    |                                    |  |
| grass (0-absent, 5-strong)    | 0 - water          | 5 - fresh herb, grass              |  |
| hay (0-absent, 5-strong)      | 0 - water          | 5 - air-dried vegetation, hay      |  |
| FRUITY                        |                    |                                    |  |
| cooked fruit pear/quince (ma  |                    | 5 - cooked fruit                   |  |
| raisins (0-absent, 5-strong)  | 0 - water          | 5 - raisins (brand, grape variety) |  |
| OTHERS SENSATIONS             |                    |                                    |  |
| adstringent (0-absent, 5-stro | 0 - water          | 5 - Baobab powder sample           |  |

During consecutive training sessions, the panel was exposed to different Baobab samples and tried to identify all (or part of) the aforementioned attributes. Subsequently, the panel was presented with selected samples of Baobab and based on the list, they had to identify and quantify the main descriptors using a 0 to 5 continuous scale (100 mm) – in which 0 stands for none and 5 for strong. At each session, samples labelled with three digit random numbers and served in transparent plastic cups (50 mL), were present at each panellist monadically according to a balanced design. Mineral water was available for rinsing between samples.

#### **Focus Group**

In order to gain insights on consumer's perception towards Baobab drinks, one small focus group was run in Porto (Portugal) during November (2012) with 9 recruited volunteers. All the participants in this study signed a consent form and an information sheet, ensuring confidentiality of information and voluntary participation.

The focus group was performed with an experienced moderator who besides the neutrality also promoted empathy within participants. The native language of participants was used and then the results translated to English. The focus group took place in a pleasant room, with a round table and a comfortable environment. All participants received a reward in order to thanks their participation.

Participants were selected when fulfilling the following requirements: a) Fruit juice consumers (at least twice a week) and b) Responsible for buying food stuffs (at least once a month). The characterization of participants is as follows as the Table below.

Table 26 – Focus group participant's demographic profile

| Demographics               | Participants (%) |
|----------------------------|------------------|
| Male                       | 44%              |
| Female                     | 56%              |
| Age 25-50                  | 100%             |
| Single                     | 44%              |
| Married                    | 56%              |
| Higher degree education    | 55%              |
| Secondary degree education | 45%              |

A Focus Group script was developed based on state of the art on the methodology. The themes exploited in Focus Groups are presented in Table 27.

Table 27 – Theme on the Focus Groups script

| Exploited Topics of Focus Groups             |
|--|
| A. Global sensory characterization           |
| B. Attitude to buy                           |
| C. Consumption occasion                      |
| D. Consumption Motives                       |
| E. Willingness to pay                        |
| F. Local to buy                              |
| G. Others possible usages of Baobab          |
| H. Influence of African Origin on preference |

The focus group discussion began with a global sensory characterization of Baobab in order to assess the impact of a first sensory experience on the acceptance of Baobab drinks. With that in mind, four blind different Baobab drink samples were tasted and

evaluated by participants, who were asked to do a global characterization of each sample, and to rank them by preference liking. The samples evaluated were:

Sample A – Commercial Juice "Esteval" (ready-to-drink)

Sample B – Commercial Syrup "Esteval"

Sample C – Commercial Syrup "Kumba"

Sample D – Traditional instantaneous powder (previously prepared with boiled water)

The focus group discussion were DVD recorded and all records were later transcripted verbatim to text, and contented analysed with software NVivo, to outline findings and meet research goals for this stage.

Figure 28 – Focus Group photography.

# **Consumer study**

Participants were recruited considering their interest and availability to participate in the study. At recruitment stage, information about the specific aim of the study was provided.

Consumers (n=100) were interviewed at a public local shopping center using the central location method (Meilgaard et al., 2007).

Three Baobab drinks were selected for consumer tasting among the samples used for sensory analysis, namely:

- 1. Traditional boiled instantaneous powder
- 2. Commercial juice from Esteval
- 3. Commercial syrup from Kumba

Consumers were asked to score their overall liking, concerning global appreciation, appearance, smell and taste of each sample on a 9-point hedonic scale (1 = "dislike extremely, 9 = "like extremely"); sweetness of each product using the 9-point "Just About Right" (JAR scale) and their willingness to buy on a 5-point scale (1 = "certainly I would not buy", 5 = "Certainly I would buy"); and to answer a Check-All-That-Apply (CATA) questionnaire that included 29 sensory and emotional terms.

Consumers were asked to check all the terms they considered appropriate to describe each of the samples. The terms were selected based on previous studies (sensory evaluation and focus-group) published data and marketing campaigns of Baobab in African market. As shown in Table 29, the terms considered in the CATA question were grouped into two categories: sensory characteristics (n=17) and emotional associations (n=12).

Table 29 - List of attributes considered in CATA question.

| SAMPLE             |  |  |
|--------------------|--|--|
| APPERANCE          |  |  |
| Amber colour       |  |  |
| Salmon-pink colour |  |  |
| Gold               |  |  |
| Turbid             |  |  |
| Viscous            |  |  |
| Fluid              |  |  |
| SMELL AND TASTE    |  |  |
| Sweet              |  |  |
| Acid               |  |  |
| Adstringent        |  |  |
| Green fruit        |  |  |
| Grass/Hay          |  |  |
| Marmalade/jelly    |  |  |
| Cooked fruit       |  |  |
| Pear nectar        |  |  |
| Raisins            |  |  |
| Caramel            |  |  |
| Guava              |  |  |
| SENSATIONS         |  |  |
| Natural            |  |  |
| Artificial         |  |  |
| Fresh              |  |  |
| Watery/Diluted     |  |  |
| Instantaneous      |  |  |
| Syrup/Concentrated |  |  |
| Fibres             |  |  |
| Healthy            |  |  |
| Functional food    |  |  |
| Pleasant           |  |  |
| Unpleasant         |  |  |
| Tropical/Exotic    |  |  |

# Data analysis

An analysis of variance (ANOVA) was performed on sensory and consumer overall liking scores considering assessor and sample as fixed source of variation. Mean ratings and honestly significant differences were calculated using Tukey's test, and were considered significant when  $p \le 0.05$ .

A principal component analysis (PCA) was also performed on the correlation matrix of the means of the trained assessors' data.

All records from focus group were later transcripted verbatim to text, and contented analysed with software NVivo.

In order to identify groups of consumers with similar preference patterns, a hierarchical cluster analysis was performed on overall liking data. Euclidean distances and Ward's aggregation method were considered.

For the CATA study, frequencies of mention for each word were determined by counting the number of consumers that used that word to describe each Baobab drink.

A multiple factor analysis (MFA) was performed on responses to the CATA question in order to identify relationships between the terms and the samples and to get a sensory map of the samples (Bécue-Bertaut and Pagès 2008). This analysis was performed on the frequency table that contained responses for each category of terms of the CATA question, considering consumer overall liking scores as supplementary variable. In this analysis, the different categories of terms from the CATA question were considered as separate groups of data to investigate the relationship between them.

Finally, external preference mapping was used to link consumer overall liking scores and responses to the CATA question. A density plot of consumer liking was created, identifying the percentage of consumers satisfied with samples.

All statistical analyses were performed using software NVivo, SPSS 19 and XLSTAT 2012.

#### **Results and Discussion**

# **Sensory evaluation**

Qualitative Descriptive Analysis (QDA) was performed in order to establish a sensory profile of Baobab drinks (Figure 29). Highly significant differences (P<0,001) between the samples were found for all the evaluated sensory attributes.

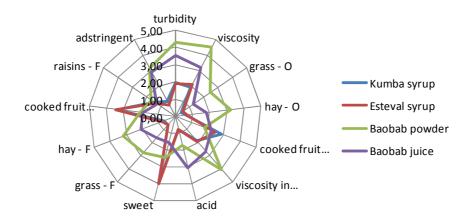

Figure 29 - Sensory profile (QDA) of Traditional boiled instantaneous powder; Commercial juice from Esteval; Commercial syrup from Esteval and Commercial syrup from Kumba.

Traditional boiled instantaneous powder is characterized by high turbidity and viscosity scores, grass, hay and astringent attributes. Commercial juice from Esteval is represented by high turbidity and viscosity levels (less than previous sample), acid and astringent descriptors.

Regarding Commercial syrups from Esteval and Kumba, both samples are described by their cooked fruit pear/quince (marmalade) and sweet sensory attributes.

Sensory profile of Traditional boiled powder is more complex then sensory profiles of Commercial juice from Esteval and from Commercial syrups from Esteval and Kumba. The later ones have the same sensory profile.

Principal component analysis (PCA) was performed to summarize the relationship between the sensory attributes and the Baobab drinks (Baobab powder, Baobab juice, Kumba syrup and Esteval syrup). The first two principal components (PCs) accounted for by 83,15 % and 15,45 % of the variance of the experimental data, respectively. As shown in Figure 30, the first PC was positively correlated to Baobab powder with viscosity, grass and hay attributes and to Baobab juice with acid and astringent descriptors. On the other hand, the second PC was related to sweet and cooked fruit pear/quince (marmalade) sensory attributes being associated with Kumba and Esteval Syrups.

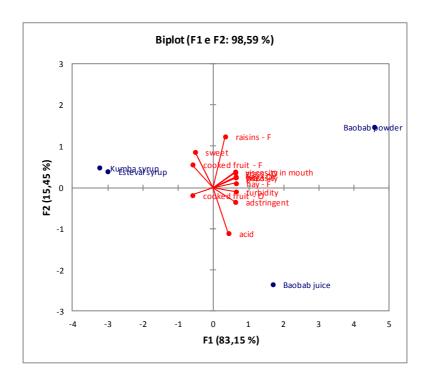

Figure 30 - Principal Component Analysis of trained assessor's sensory data (representation of sensory attributes and Baobab samples).

# **Focus Group**

#### 1. Global Characterization of Baobab Drink

Briefly is presented next a liking characterization based on the speech of the participants, after tasting and evaluating each sample:

**Sample A** – Commercial Juice from "Esteval" (ready to drink) – This was the most preferred sample selected by participants. This sample was valued because of its taste, although they think its bit acid.

Related to the aroma it was not highly appreciated, because they expected to be more fruity. They classified it as neutral aroma, not strong enough and dry, and what seemed like a vegetal aroma remembering straw. The colour does not also convince the participants because was colourless and slight.

**Sample B** – Commercial Syrup from "Esteval" – This sample, in general, was not appreciated by the participants, because it is too concentrated and too sweet. It was categorized like a sweet watery of cooked apple, and they think it should be stickier. The taste was associated to caramelized sugar and also to locust bean.

**Sample C** – Commercial Syrup from "Kumba" – This sample was also not very much appreciated by the participants, by the same reasons of sample B: too concentrated, too sweet, watery, tasteless and odourless.

**Sample D** – Traditional boiled instantaneous powder (no reference) – This sample was the second favourite of this group, but the texture should be indeed changed, otherwise they would not drink it at all. This sample had small pieces of seeds which participants are not used to and immediately rejected. The global appearance was similar to nectars, but still they think it should be improved. They expected a better aroma.

As presented on Table 30, regarding to the description of attributes generated two groups were elicited according to the positive and negative opinion of participants.

It was referred that in a general terms this drink is not yet suited for European kids and that is also do not suitable as a summer drink.

Table 30 – Attributes generated during the Focus Group

| Sensory               |  |
|-----------------------|--|
| Sweetness             |  |
| Acid                  |  |
| Watery                |  |
| Bitter                |  |
| Food Related Positive |  |
| Apple                 |  |
| Pear                  |  |
| Caramel               |  |

| Locust bean               |
|---------------------------|
| Fibre                     |
| Peache                    |
| Food Related Negative     |
| Animal Feed               |
| Non-Food Related Negative |
| Syrup/Medication          |
| Straw                     |

# 2. Attitude to Buy

In this item it was evaluated the frequency of consumption if this beverage would be available on the Portuguese market. The answers show that participants are divided in four distinct groups: 33% would not buy this drink as it is in their original African form; 33% would buy it 2 times/week; 23% would be willing to buy it once a week and 11% would buy it sporadic way, like 2 times in a month.

# 3. Occasion and Local for consumption

The Table 31 below summarize the main occasions and places for Baobab Drink consumption for Portuguese consumers.

Table 31 – Identified occasion and places for Baobab drink consumption

| Occasion for consumption           | Frequency (%) |
|------------------------------------|---------------|
| Breakfast                          | 55%           |
| Middle of afternoon                | 33%           |
| Any meal                           | 11%           |
| <b>Locals for Consumption</b>      |               |
| Home                               | 33%           |
| Outside (cafes, bars, restaurants) | 78%           |
|                                    |               |

#### 4. Motives for consumption

Healthy benefits are the main reason that might convince Portuguese consumers to buy Baobab Drink. This motive had 89% frequency, including participants stating they would not buy the product as it is now in its original form. Participants knew in advanced that Baobab has in its composition a high antioxidant capability mainly because of its high natural vitamin C content, which protects the cells of organisms from damage by free radicals (Gruenwald, 2005). So as this component is very important for human health they do not hesitate in drinking it even if the taste was not as pleasant as they expected. Besides the apparently low acceptability of same samples, taste (44%) and texture (33%) were also mentioned as important reasons that lead consumption. Novelty was also refereed (33%) but this motive has to be interpreted carefully once novelty works normally for first times of consumption.

# 5. Willingness to pay

Regarding willingness to pay for Baobab Drink, 44% of participants see themselves buying 1 L tetra-pack packages in supermarkets, and the range price varies between  $1.00 \leftarrow 1.39 \neq /$  L.

Moreover, about 78% see themselves buying small packages of 0,33cl in cafes/bars, where they would be willing to pay between 0,85€-15€/package. The preferred material for the small package is glass (44%), tetra-pack and plastic were also referred (11%), but cans were not mentioned for this type of drink as preferred to.

#### 6. Locals to Buy

Consists on locals where consumers would like to have Baobab drink available to buy, about 67% said in cafes and bars; supermarkets are mentioned in second place (56%); also restaurants were refereed but with a lower percentage (33%). In addition, convenience shops, gas station shops and delicatessen shops where also referred each one representing 11% of frequency.

#### 7. Possible applications

The Table 32 below resume the frequency and applications proposed by the participants. The suggestions presented were aggregated in two distinct groups according the application's type.

Table 32 – Possible uses for product type of Baobab

| Applications Type | Product Suggestion              | Frequency |
|-------------------|---------------------------------|-----------|
| Agro-Industries   | Yogurt (liquid or with cereals) | 44%       |
|                   | Cookies                         | 22%       |

|            | Cereal Bars | 11%  |
|------------|-------------|------|
|            | Soya Drink  | 11%  |
|            |             |      |
| House maid | Jelly       | 33 % |
|            | Fruit Tart  | 11 % |
|            |             |      |

# 8. Influence of the origin

Concerning the importance and influence to consumers' choice of drinks origin's in labelling, it seems that for the majority of the participants (56%) these agreement it might be very positive the mention "African Origin" in the label, adding value to the product and also curiosity to the consumers, to taste a product from such a different culture.

# **Consumer study**

# 1. Consumer Overall liking scores

As shown in Table 33, there were not significant differences (P>0,05) in the overall liking scores. Regarding all samples used during consumer study it was possible to verify that all of the drinks were on the acceptable range since the mean scores were between 6 (like moderately) and 7 (like slightly). Baobab juice was the most preferred followed by Kumba syrup and Baobab powder, in a decrease order of magnitude.

Table 33 - Mean overall acceptability scores for the Baobab drinks tested.

| Samples                  | Average | Groups * |
|--------------------------|---------|----------|
| Sample A - Baobab Juice  | 6,530   | Α        |
| Sample B - Kumba syrup   | 6,490   | Α        |
| Sample C - Baobab Powder | 6,050   | Α        |

<sup>\*</sup> Means with the same letter are not significantly different

# 2. Consumers segmentation using Hierarchical cluster analysis

The hierarchical cluster analysis (Ward method) identified three groups of consumers that scored the overall liking scores of the samples differently: Cluster 1 with 38 individuals, Cluster 2 with 48 and Cluster 3 with 14 consumers (Figure 31).

There were significant differences (P < 0.001) in the overall liking of the clusters, indicating different preference patterns (Table 34). Consumers in Cluster 1 gave the highest overall acceptability scores to Kumba syrup sample followed by Baobab juice and Baobab powder; Cluster 2 evaluated with highest scores Baobab powder followed by Baobab juice and Kumba syrup; and Cluster 3 attributed the highest scores to Kumba syrup sample followed by Baobab juice and Baobab powder.

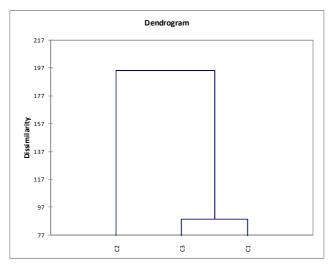

Figure 31 - Hierarchical cluster analysis of Baobab drinks consumers.

Table 34 - Baobab samples distributed into Cluster sorted by increasing order of preference.

# Objects sorted by increasing order of preference

| Cluster 1              | Cluster 2              | Cluster 3              |
|------------------------|------------------------|------------------------|
| Sample C - Powder      | Sample B - Kumba syrup | Sample C - Powder      |
| Sample A - Juice       | Sample A - Juice       | Sample A - Juice       |
| Sample B - Kumba syrup | Sample C - Powder      | Sample B - Kumba syrup |

# 3. Check-All-That-Apply Question

Consumers were asked to evaluate the samples and to check all the terms that they considered appropriate to describe the sensory characteristics and emotional associations/perceptions using a questionnaire comprising 29 related terms. The most frequently selected terms were considered as the most used by consumers to describe the samples.

Table 35 shows the frequency in which each of the terms of the CATA question was used to describe the evaluated samples. The most frequently used terms were "sweet", "natural", "enjoyable/pleasant", "healthy", "tropical/exotic", "turbid", "amber colour", "marmalade/jelly", "pear nectar", "salmon-pink colour" and "fresh". Meanwhile, the least used terms were "caramel", "raisins" and "grass/hay".

Significant differences (P<0,0001) were found in the number of terms used by consumers to describe the samples. As shown in Table 35, the largest number of terms was used to describe Samples C - Baobab powder, B - Kumba syrup followed by A - Baobab juice. This could be explained considering that consumers were more motivated/interested to describe the samples that they considered more complex, it means, samples with a wide range/bouquet of words to describe the moment of tasting. Regarding the different categories in the CATA question, consumers used the terms related to the sensory characteristics of samples with a higher frequency than those within the emotional associations; suggesting that consumers' perception was mostly centred in their sensory characteristics.

These results suggest that this type of question was able to detect differences in consumer's perception of the Baobab drinks.

Table 35 - Results of the Check-All-That-Apply question. Frequencies for each attribute and evaluated Baobab samples.

| Category            | Attributes   | Sample A - | Sample B -<br>Kumba syrup | Sample C -<br>Powder | Frequency of mention | Frequency of mention/category | Average number of mentions/category |
|---------------------|--|------------|---------------------------|----------------------|----------------------|-------------------------------|-------------------------------------|
|                     | Amber colour   | 36         | 25                        | 27                   | 88                   | 9 *                           |                                     |
|                     | Salmon-pink colour   | 43         | 8                         | 30                   |                      |                               |                                     |
|                     | Gold   | 6          | 48                        | 2                    | 56                   |                               |                                     |

|                     | Tropical/Exotic  | 31         | 23                        | 42                   | 96                   |                               |                                     |
|                     | Total terms/sample   | 608        | 691                       | 817                  |                      |                               |                                     |
|                     | Average number of<br>terms used in CATA<br>question/sample | 6,08       | 6,91                      | 8,17                 |                      |                               |                                     |

Considering that the two identified clusters showed different preference patterns, they could have also used the terms of CATA question differently. Therefore, Multiple Factor Analysis (MFA) was carried on out considering CATA counts for both groups of consumers. Multiple factor analysis (MFA) was performed on responses in each category of the CATA question in order to identify relationships between the terms and the samples and to get a sensory map of the samples.

In what concerns sensory characteristics category, the first two dimensions of the MFA accounted for 100% of the variance of the experimental data; representing 62,92% and 27,08% of the variance for the first and second dimension, respectively. Regarding emotional associations category, the first two dimensions of the MFA accounted for 100% of the variance of the experimental data; representing 77,31% and 22,69% of the variance for the first and second dimension, respectively.

Figure 32 a) shows the representation of the sensory terms from the CATA question in the first and second dimensions of the MFA of CATA counts. The first dimension of the MFA was positively correlated to terms gold, fluid, caramel and sweet related to sample B - Kumba syrup; and negatively associated to pear nectar, marmalade/jelly, viscous and raisins attributes represented by sample C - Baobab powder; and negatively correlated to amber colour and acid attributes related to sample A - Baobab juice. On the other hand, the second dimension was positively correlated to sweet, fruity and fresh herb representative of syrup sample.

Figure 32 b) shows the representation of emotional associations terms from the CATA question in the first and second dimensions of the MFA of CATA counts. The first dimension of the MFA was positively correlated to syrup/concentrated, fibres, natural, healthy, functional food and tropical/exotic terms being associated with sample C - Baobab powder; and negatively correlated to artificial, fresh, watery/diluted and instantaneous

| Unpleasant         | AT28 |  |  |  |
| Tropical/Exotic    | AT29 |  |  |  |

descriptors from sample B - Kumba syrup. Sample A - Baobab juice was positively represented in the first dimension of the MFA with no terms associated. Nevertheless, Sample A - Baobab juice maybe represented with enjoyable/pleasant and tropical/exotic terms.

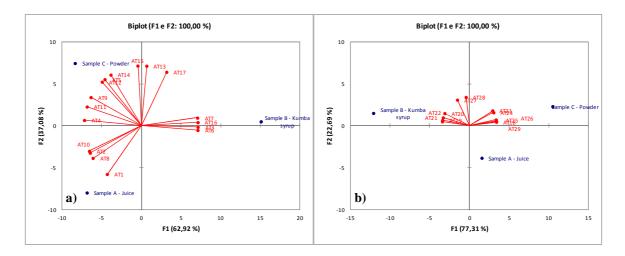

Figure 32 - Multiple Factor Analysis on the Check-All-That-Apply questions a) representation of the attributes for sensory characteristics category and b) representation of the attributes for emotional association category.

Since different categories of terms were included in the CATA question, samples were characterized not only in terms of sensory attributes, but also considering consumer perception of different aspects of the samples (emotional associations) and the overall liking of each one. The relationship between the categories of terms from the CATA question provided interesting information. As shown in Figure 33, all the categories were located close to each other in the first dimension of the MFA, which suggests that they provided similar information. MFA accounted for 100% of the total variance of the experimental data; representing 67,59% and 32,41% of the variance for the first and second dimension, respectively. However, it is interesting to note that the group of terms related to emotional associations (sensations/perceptions) and the overall liking were highly correlated. This suggests that sensations/perceptions during degustation seemed to have influenced consumers' overall liking responses to Baobab drinks. Moreover, these two groups of terms were highly correlated to sensory properties; suggesting that sensory characteristics were the main determinants of consumers' hedonic and emotional response toward the evaluated Baobab drinks.

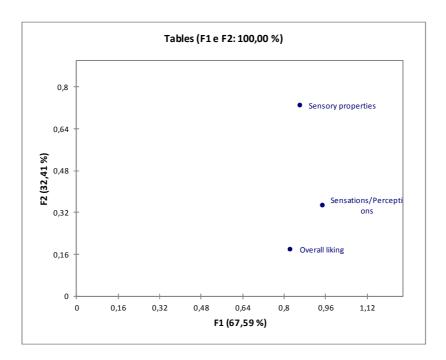

Figure 33 - Representation of the categories of terms from the CATA question and the overall liking scores in the first two dimensions of the MFA.

The approach of considering different categories of terms in a CATA question seems promising for studying the relationship of consumers' perception of sensory and non-sensory attributes of products. This is an interesting approach for R&D, Marketing and Communication departments to develop strategies for launching a new/or changed product to market. So, to more finely compare the level of agreement/disagreement between all categories considered on CATA question and overall liking scores, MFA was employed using the first two dimensions of the three maps created. Figure 34

represents the location of the Baobab drinks as optimal product determined for each of the three types of categories on the first two MFA factors (individual factor map).

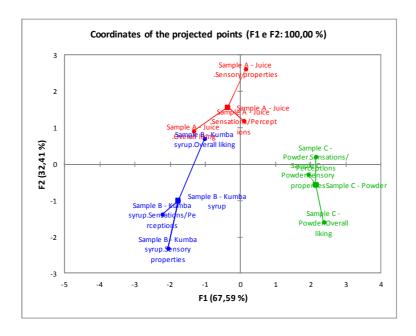

Figure 34 - Products' spatial representation /products' configuration (first two dimensions) determined using sensory characteristics, emotional associations and overall liking scores of consumers.

# 4. External Preference Mapping

External preference map (and contour plot) based on samples' configuration in the MFA of CATA counts was impossible to perform since it is need more observations (individuals). As mentioned in section "consumer overall liking scores", there were not significant differences (P>0,05) in the overall liking scores of presented samples. In this way, it was only possible to determine the percentage of individuals satisfied for each sample (Table 35).

Table 35 - Percentage of consumers satisfied for each sample.

| Samples                | %   |
|------------------------|-----|
| Sample A - Juice       | 67% |
| Sample B - Kumba syrup | 67% |
| Sample C - Powder      | 33% |

# 5. Internal Preference Mapping

Figure 35 shows the internal preference map based on consumers' overall liking of

Baobab drinks.

Consumers

Sample C

30

| Sample C | 30 | 30% |
| sample B | 27 | 27% |
| Sample A | 22 | 22% |
| no opinion | 21 | 21% |
| 100 |

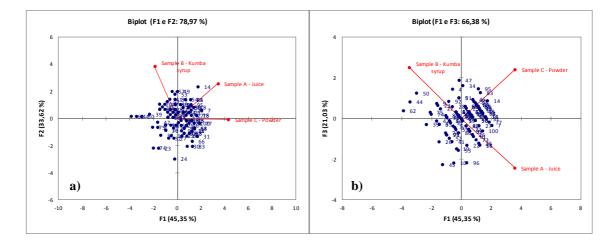

Figure 35 - Internal Preference Map based on consumers' overall liking samples.

The internal preference map showed four groups of consumer's preference: Group I - sample C - Baobab powder with 30%, Group II - Sample B - Kumba syrup with 27%, Group III - Sample A - Baobab juice with 22% and Group IV with no opinion with 21%, of overall liking scores.

#### **Conclusions**

Unfamiliarity with respect to taste of Baobab, the first global perception implies that the product needs reengineering to be adapted to the Portuguese market, especially regarding to the texture and aroma attributes.

Sample configuration from consumers' CATA counts and trained assessors data were similar, suggesting a good agreement between both evaluations. The use of CATA questions could be a simple way to perform external preference mapping when a sensory trained panel is not available or when there is not enough time to train a sensory panel. In this way, the use of the CATA question could consist on a complementary technique to traditional preference mapping.
